The Supplementary Information consists of four sections. In the first section, “1D HET-RFDR Experiments” we show additional 1D  $^1\text{H}$ - $^{13}\text{C}$  HET-RFDR spectra. The second “HET-RFDR Simulations” section provides additional HET-RFDR simulations, which were performed under conditions that closely match the experiments. The third section, “Operator Paths” shows the possible paths of RFDR and HET-RFDR transfers via heteronuclear and homonuclear operators during the first two rotor periods. The last part, “RFDR Phase Cycling”, shows the formal proof of zero signal transfer for a homonuclear  $I_2$  spin system with zero offset difference and when all  $\pi$ -pulses have the same phase.

## **1D HET-RFDR Experiments**

Figure S1 shows a 1D HET-RFDR pulse sequence. The sequence consists of two  $\pi/2$ -pulses on the  $^1\text{H}$  channel (with two step phase cycling to eliminate the signal from directly excited spins of carbons) followed by a series of HET-RFDR pulses and finally a  $\pi/2$ -pulse and detection on the  $^{13}\text{C}$  channel. The evolution of the magnetization from proton to carbon spins through the HET-RFDR pulse sequence (Figure S1) can be described with cartesian operators as follows:

$$22 \quad H_z \xrightarrow{\text{first proton } \left(\frac{\pi}{2}\right)_x \text{ pulse}} -H_y \xrightarrow{\text{second proton } \left(\frac{\pi}{2}\right)_{\mp x} \text{ pulse}} \pm H_z$$

$$23 \quad \xrightarrow{\text{HET-RFDR block}} \pm a_{HC}(t_{mix})C_z \xrightarrow{\text{first carbon } \left(\frac{\pi}{2}\right)_x \text{ pulse}} \mp a_{HC}(t_{mix})C_y \xrightarrow{\text{detection}_{\pm x}} -a_{HC}(t_{mix}), \quad \text{Eq. (S1)}$$

24 where,  $a_{HC}(t_{mix})$ , is an amplitude of the transferred signal.

## 1D HET-RFDR

25

26 **Figure S1** 1D HET-RFDR pulse sequence. The sequence consists of two  $\pi/2$ -pulses on the  $^1\text{H}$  channel, HET-RFDR blocks ( a  
 27 train of  $\pi$ -pulses with a single pulse during each rotor period applied on both channels),  $\pi/2$ -pulse on the  $^{13}\text{C}$  channel and  
 28 detection with proton decoupling. The phases of the  $\pi/2$ -pulses are  $\varphi_1 = x$ ;  $\varphi_2 = -x, x$ ;  $\varphi_3 = -x, -x, x, x, y, y, -y, -y$ .  $\varphi_{acq} =$   
 29  $x, -x, -x, x, -y, y, y, -y$ .  $\pi$ -pulses on the both channels follow the XY8 scheme (Gullion et al., 1990). During acquisition, SWH-  
 30 TPPM (Thakur et al., 2006) at 55.555 kHz or SPINAL64 (Fung et al., 2000) at 10 kHz decoupling is applied on the proton  
 31 channel to narrow the detected resonances.

32 Figures. S2-S3 demonstrate 1D HC HET-RFDR spectra using [ $^{13}\text{C}$ ,  $^{15}\text{N}$ ] labeled SH3. On proton  
 33 and carbon channels  $\pi$ -pulses with different lengths were applied: 3.4 us (147 kHz) and 5 us (100 kHz),  
 34 respectively. Figure S2a shows HC spectra under different mixing times: 0.576 ms, 1.728 ms, 2.888 ms,

35 4.032 ms, 5.184 ms and 6.336 ms. Figure S2b shows HC spectra, which were obtained with 6.336 ms  
 36 HET-RFDR (blue) and RFDR (cyan,  $\pi$ -pulses were applied on carbon channel only) . As expected, HET-  
 37 RFDR provides  $^1\text{H}$  to  $^{13}\text{C}$  transfer. The efficiency depends on the spectral region. For some aromatic  
 38 carbons, the transfer achieves  $\sim 100\%$  efficiency with respect to CP at 1.5 ms (Figure S2b, red), but for  
 39 other regions, like  $\text{C}\alpha$ , the polarization transfer is  $\sim 50\%$ .

40  
 41 **Figure S2** 1D HC [ $^{13}\text{C}$ ,  $^{15}\text{N}$ ] labeled SH3 spectra at 55.555 kHz (a) HET-RFDR spectra with different mixing times: 0.576 ms,  
 42 1.728 ms, 2.888 ms, 4.032 ms, 5.184 ms, 6.336 ms. (b) Comparison of 1D HC CP spectrum (red, 1.5 ms of CP mixing) and  
 43 HET-RFDR spectrum (blue, 6.336 ms of HET-RFDR mixing). The cyan spectrum shows a HC RFDR spectrum, for which  $\pi$ -  
 44 pulses were applied only on the  $^{13}\text{C}$  channel. The carbon reference frequency was set up on 40 ppm. The MAS rate was 55.555  
 45 kHz. The experimental parameters are shown in Table S1.

46 The transfer of the magnetization from  $H_z$  operators to  $C_z$  operators is minimally affected by flip  
 47 angle deviations, since XY8 phase cycling is used (Gullion et al., 1990). To show this, we recorded  
 48 additional 1D HC HET-RFDR spectra with a series of flip angles on the carbon channel. (Figure S3).

49

50 Figure S3 1D proton-carbon HET-RFDR spectra of [<sup>13</sup>C, <sup>15</sup>N] labeled SH3 with a 6.336 ms transfer time as a function of the  
 51 flip angle of the pulses on the carbon channel between 157.34° and 184.64° (17 spectra). The width of  $\pi$ -pulses on the proton  
 52 channel was 3.4  $\mu$ s. The width of the applied pulses on the carbon channel was constant and equal to 5  $\mu$ s. 55.555 kHz MAS was  
 53 used. The rf-field values in kHz on the carbon channel from left to right were: 87.41, 88.2, 89.01, 89.83, 90.66, 91.51, 92.38,  
 54 93.26, 94.16, 95.08, 96.02, 96.97, 97.94, 98.94, 99.95, 100.98, 102.04.

55 *Solid state NMR spectroscopy:* The CP and HET-RFDR spectra of <sup>13</sup>C,<sup>15</sup>N SH3 were acquired at 14.1 T  
 56 (600 MHz) using a Bruker AVIIIHD spectrometer using a MASDVT600W2 BL1.3 HXY probe. The  
 57 experiments were performed at 55.555 kHz MAS with the temperature of the cooling gas set to 235 K.

58 For 1D <sup>1</sup>H<sup>13</sup>C spectra during the HET-RFDR periods, the widths of pulses on proton and carbon channels  
 59 were 3.4  $\mu$ s and 5  $\mu$ s, respectively. 13.89 kHz SW<sub>f</sub>-TPPM (Thakur et al., 2006) with 36  $\mu$ s pulses was used  
 60 during the acquisition. Table S1 summarizes the applied experimental parameters.

61 **Table S1** Summary of the experimental parameters used in the CP (the start and the end values are shown) and HET-RFDR H<sup>13</sup>C  
 62 [<sup>13</sup>C,<sup>15</sup>N] SH3 experiments.

	CP	HET-RFDR
$^1\text{H}$ (kHz)	92-115	147
$^{13}\text{C}$ (kHz)	43	100, [87.41-102.04]
transfer time (ms)	1.5	[0.576-6.336]
NS	48	48
D1 (s)	1.5	1.5
AQ (s)	0.01536	0.01536
SW (kHz)	50	50

63 NS – number of scans; D1 – a recycle delay; AQ – the acquisition time; SW – the spectral width.

## 64 HET-RFDR Simulations

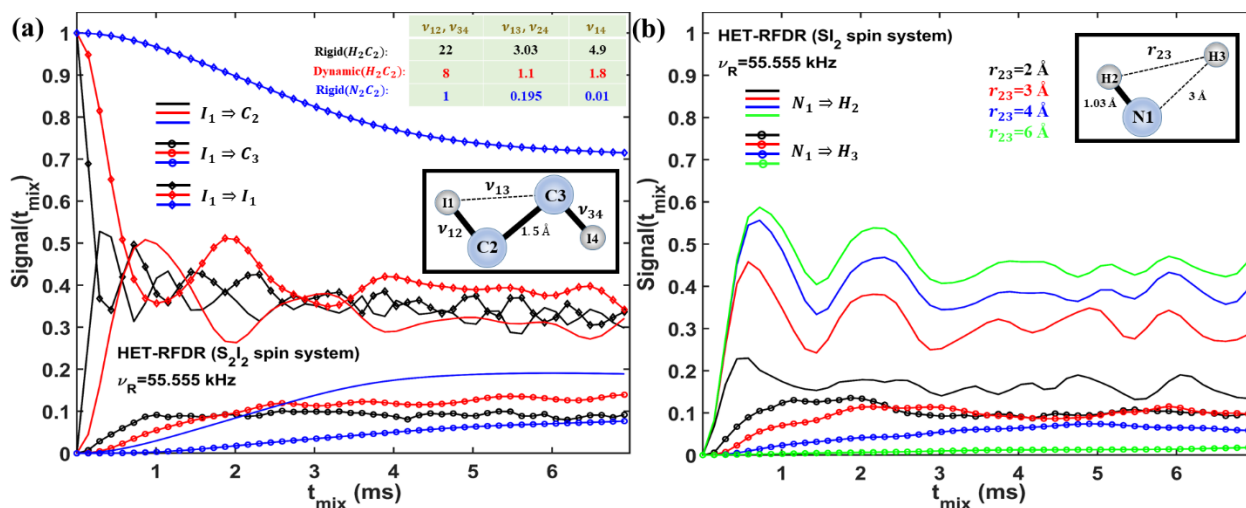

65 Figure S4 shows simulated HET-RFDR polarization transfers for four ( $S_2I_2$ , Figure S4a) and three ( $SI_2$ ,  
66 Figure S4b) spin systems with conditions that closely match the experiments: 55.555 kHz MAS and 5.4  
67  $\mu\text{s}$   $\pi$ -pulses.

68 Figure S4a shows the HET-RFDR polarization transfers between a directly bonded spin pair ( $I_1$ - $C_2$ , solid  
69 lines) and the remote pair ( $I_1$ - $C_3$ , lines with circles). The lines with diamonds represent signals that are not  
70 transferred, but remain on the spin  $I_1$ . We consider three cases: rigid  $C_2H_2$  chain (black lines), dynamic  
71  $C_2H_2$  chain (red lines) and rigid  $N_2C_2$  chain (blue lines). For the rigid (black solid line) and dynamic (red  
72 solid line)  $C_2H_2$  chains when the heteronuclear dipolar coupling constants are larger than the homonuclear  
73 dipolar constants, the polarization transfer from  $H_1$  to  $C_2$  oscillates about ~35% efficiency. However, for  
74 the spin system with the weak heteronuclear dipolar coupling constants (blue lines), the HET fp-RFDR  
75 polarization transfer between directly bonded spins is lower (blue solid line) and achieves only ~20%  
76 transfer efficiency.

77 The signal that remains on the starting spin (lines with diamonds) are ~40% for first two cases (black and  
78 solid lines with diamonds) and ~70% for weak dipolar coupling constants (blue line with diamonds).

79 The HET-RFDR transfer between remote spins, e.g.  $H_1$  and  $C_3$  are about ~10% of the initial polarization  
80 for all these three cases (black, red and blue lines with circles). The transfer of magnetization mostly  
81 occurs via relayed transfer ( $I_1$ - $C_2$ - $C_3$ ) and not directly from  $I_1$  to  $C_3$ , which more clearly can be seen in the  
82 simulations on Figure S4b

83 Figure S4b considers the HET-RFDR polarization transfer between directly bonded spins ( $N_1$ - $H_2$ , solid  
 84 lines) and remote pair ( $N_1$ - $H_3$ , lines with circles). The heteronuclear dipolar coupling constant between  $N_1$   
 85 to  $H_2$  spins is kept constant and the homonuclear dipolar constant between  $H_2$  and  $H_3$  is changed. When  
 86 the distance between  $H_2$  and  $H_3$  spins is 6 Å (green lines), the fp-RFDR polarization transfer between  $N_1$   
 87 and  $H_2$  achieves the maximal transfer of about 50% (solid green line). The direct HET-RFDR polarization  
 88 transfer efficiency between  $N_1$  and  $H_3$  is very low (green line with circles). For the  $H_2$  -  $H_3$  distances of 4  
 89 Å (blue line with circles), 3 Å (red line with circles) and 2 Å (black line with circles), the polarization  
 90 transfer between  $N_1$  and  $H_3$  achieves ~10%. Since the distance between  $N_1$  and  $H_3$  is not changed, the  
 91 transfer between  $N_1$  and  $H_3$  is achieved via sequential relayed transfer,  $N_1$ - $H_2$ - $H_3$ . The homonuclear  
 92 distance also has influence on the HET-RFDR polarization transfer. With decreased  $H_2$ - $H_3$  distance the  
 93 amplitude of the HET-RFDR polarization transfer between directly bonded spins (solid lines) is decreased.

94  
 95 **Figure S4** Simulated HET-RFDR signals. The simulated HET-RFDR polarization transfers for  $S_2I_2$  (a) and  $SI_2$  (b) spin systems  
 96 are shown as a function of mixing time. For all simulations MAS was 55.555 kHz and hard  $\pi$ -pulses with 5.4 us width (92.59  
 97 kHz rf-field) were applied simultaneously every rotor period. The offset and CSA values (the offset and CSA values are defined  
 98 in the same way as in (Bak et al., 2000)) of spins [ $I_1;C_2;C_3;I_4$ ] are [1;2;5.5;6] (kHz) and [4;1;2;3] (kHz), respectively. The initial  
 99 and the final operators were in the direction  $\hat{z}$ . (a) The solid lines represent the HET-RFDR polarization transfers between  $I_1$  and  
 100  $C_2$  spins; the lines with circles represent the HET-RFDR polarization transfers between  $I_1$  and  $C_3$  spins and the lines with  
 101 diamonds represent the decay of starting signals. The carbon-carbon distance as well as the dipolar coupling constant between  $C_2$

102 and  $C_3$  were kept unchanged at 1.5 Å (2.22 kHz). The black lines represent the rigid  $H_2C_2$  spin system (with  $I_1, I_4$  of the inset as  
 103 protons). The proton-carbon dipolar coupling constants were:  $\nu_{12} = \nu_{34} = 22 \text{ kHz}$ ;  $\nu_{13} = \nu_{34} = 3.03 \text{ kHz}$  and the proton-proton  
 104 coupling constant was:  $\nu_{14} = 4.9 \text{ kHz}$ . The red lines represent the dynamic  $H_2C_2$  spin system with reduced proton-carbon  
 105 couplings of are:  $\nu_{12} = \nu_{34} = 8 \text{ kHz}$ ;  $\nu_{13} = \nu_{34} = 1.01 \text{ kHz}$  and a reduced proton-proton coupling  $\nu_{14} = 1.8 \text{ kHz}$ . The blue  
 106 lines represent the rigid  $N_2C_2$  spin system (with  $I_1, I_4$  of the inset as nitrogens). The nitrogen-carbon dipolar coupling constants  
 107 are:  $\nu_{12} = \nu_{34} = 1 \text{ kHz}$ ;  $\nu_{13} = \nu_{34} = 0.195 \text{ kHz}$  and for the nitrogen-nitrogen coupling,  $\nu_{14} = 0.01 \text{ kHz}$ . (b) The solid lines  
 108 represent the HET-RFDR polarization transfer between  $N_1$  and  $H_2$  spins with unchanged dipolar coupling constant of 11 kHz.  
 109 The lines with circles represent the transfer between  $N_1$  and  $H_3$  spins for different distances (dipolar coupling constants) between  
 110  $H_2$  and  $H_3$  spins: black lines – 2 Å (15 kHz), red lines – 3 Å (4.4 kHz), blue lines – 4 Å (1.9 kHz) and green lines – 6 Å (0.5 kHz).  
 111 The distance as well as the dipolar coupling constant between  $N_1$  and  $H_3$  were kept unchanged at 3 Å and 0.45 kHz.

## 112 Operator Paths

113 In this section we identify the paths via which the signals are transferred from  $I_z$  to  $S_z$  operators  
 114 and from  $I_{z1}$  to  $I_{z2}$  operators during the first two rotor periods of HET-RFDR and RFDR blocks,  
 115 respectively. We consider the amplitudes of the operators that are generated as a result of the evolution of  
 116 the other operators through pulses or delays:  $t(\pi_x) \rightarrow del_1 \rightarrow t(\pi_y) \rightarrow del_2$ . We first consider the  
 117 heteronuclear case of an  $IS$  spin system during HET-RFDR. Table S2 consists of four subsections. The  
 118 first, second, third and fourth subsections represent the amplitudes of four operators,  $I_z, S_z, 2I_xS_y, 2I_yS_x$ ,  
 119 measured at four points.

120 **Table S2** Transfer paths during HET-RFDR. The single crystal amplitudes (Euler angles: 184°; 141°; 349°) of the operators at  
 121 four time points:  $\pi_x$  – the end of the first pulse;  $del_1$  – the end of the first delay;  $\pi_y$  – the end of the second pulse;  $del_2$  – in the  
 122 end of the second delay. The first column shows the initial operators. The first, second, third and fourth subsections represent the  
 123 amplitudes with the initial operators  $I_z, S_z, 2I_xS_y, 2I_yS_x$ , respectively. The used simulated parameters were as in Figure 5a in the  
 124 main text.

Op	$I_z$				$S_z$				$2I_xS_y$				$2I_yS_x$			
	$\pi_x$	$del_1$	$\pi_y$	$del_2$	$\pi_x$	$del_1$	$\pi_y$	$del_2$	$\pi_x$	$del_1$	$\pi_y$	$del_2$	$\pi_x$	$del_1$	$\pi_y$	$del_2$
$I_z$	- 0.95	1	- 0.95	1	0	0	0	0	0.31	0	0	0	0	0	- 0.31	0
$S_z$	0	0	0	0	- 0.95	1	- 0.95	1	0	0	- 0.31	0	0.31	0	0	0
$2I_xS_y$	- 0.31	0	0	0	0.31	0	0.31	0	- 0.95	1	- 0.95	1	0	0	0	0
$2I_yS_x$	0	0	0.31	0	0	0	0	0	0	0	0	0	- 0.95	1	- 0.95	1

125

126 For example, the path  $I_z \xrightarrow{\pi_x} I_z \xrightarrow{del_1} I_z \xrightarrow{\pi_y} I_z \xrightarrow{del_2} I_z$  gives the amplitude of  $-0.95 \cdot 1 \cdot (-0.95) \cdot 1 =$

127 0.9 (the bold font in the Table S2), which equals the amplitude of the  $I_z$  operator at the end of  $2T_R$  in

128 Figure 5a in the main text (black line). The path  $I_z \xrightarrow{\pi_x} I_z \xrightarrow{del_1} I_z \xrightarrow{\pi_y} I_z \xrightarrow{del_2} S_z$  gives the amplitude of

129  $-0.95 \cdot 1 \cdot (-0.95) \cdot 0 = 0$ . If we analyze all 64 possibilities, we find only one heteronuclear path,

130 connecting  $I_z$  and  $S_z$  operators through the first two rotor periods of HET-RFDR:  $I_z$

131  $\xrightarrow{\pi_x} 2I_x S_y \xrightarrow{del_1} 2I_x S_y \xrightarrow{\pi_y} S_z \xrightarrow{del_2} S_z$  with nonzero amplitude of  $-0.31 \cdot 1 \cdot (-0.31) \cdot 1 = 0.097$ .

132 In the same way we tabulate the homonuclear  $I_2$  spin system during the first two rotor periods of

133 RFDR block in Table S3.

134 **Table S3** Transfer paths during RFDR. The single crystal amplitudes (Euler angles:  $184^\circ$ ;  $141^\circ$ ;  $349^\circ$ ) of the operators at four

135 time points:  $\pi_x$  – the end of the first pulse;  $del_1$  – the end of the first delay;  $\pi_y$  – the end of the second pulse;  $del_2$  – the end of

136 the second delay. The first column shows the initial operators. The first, second, third and fourth subsections represent the

137 amplitudes with the initial operators  $I_{z1}$ ,  $I_{z2}$ ,  $2I_{x1}I_{y2}$ ,  $2I_{y1}I_{x2}$ , respectively. The simulated parameters were as in Figure 5b in the

138 main text.

Op	$I_{z1}$				$I_{z2}$				$2I_{x1}I_{y2}$				$2I_{y1}I_{x2}$			
	$\pi_x$	$del_1$	$\pi_y$	$del_2$	$\pi_x$	$del_1$	$\pi_y$	$del_2$	$\pi_x$	$del_1$	$\pi_y$	$del_2$	$\pi_x$	$del_1$	$\pi_y$	$del_2$
$I_{z1}$	- 0.97	0.96	- 0.97	0.96	0.02	0.04	0.02	0.04	0.1	-0.2	- 0.21	-0.2	0.21	0.2	-0.1	0.2
$I_{z2}$	0.02	0.04	0.02	0.04	- 0.97	0.96	- 0.97	0.96	0.21	0.2	-0.1	0.2	0.1	-0.2	- 0.21	-0.2
$2I_{x1}I_{y2}$	-0.1	0.21	0.21	0.2	- 0.21	-0.2	0.1	-0.2	- 0.97	0.96	- 0.97	0.96	0.02	0.04	0.02	0.04
$2I_{y1}I_{x2}$	- 0.21	-0.2	0.1	-0.2	-0.1	0.2	0.21	0.2	0.02	0.04	0.02	0.04	- 0.97	0.96	- 0.97	0.96

139

140 Unlike the  $IS$  spin system, all 64 paths have nonzero amplitudes via which the signal is

141 transferred from homonuclear operator  $I_{z1}$  to operator  $I_{z2}$  during the first two rotor periods of RFDR.

142 These 64 paths can be divided into four groups.

143 The first group contains eight paths with combinations of  $I_{z1}$ ,  $I_{z2}$  operators only. For example, the  
 144 path  $I_{z1} \xrightarrow{\pi_x} I_{z1} \xrightarrow{del_1} I_{z1} \xrightarrow{\pi_y} I_{z1} \xrightarrow{del_2} I_{z2}$  has 0.0393 amplitude, whereas the path  $I_{z1}$   
 145  $\xrightarrow{\pi_x} I_{z2} \xrightarrow{del_1} I_{z2} \xrightarrow{\pi_y} I_{z2} \xrightarrow{del_2} I_{z2}$  has -0.0195 amplitude. The total amplitude of this group is 0.03920388.

146 The second group contains 24 paths where each of the paths contains one of the operators  $2I_{x1}I_{y2}$   
 147 or  $2I_{y1}I_{x2}$ . For example, the path  $I_{z1} \xrightarrow{\pi_x} I_{z1} \xrightarrow{del_1} I_{z1} \xrightarrow{\pi_y} 2I_{x1}I_{y2} \xrightarrow{del_2} I_{z2}$  has -0.0393 amplitude, whereas the  
 148 path  $I_{z1} \xrightarrow{\pi_x} I_{z1} \xrightarrow{del_1} 2I_{x1}I_{y2} \xrightarrow{\pi_y} I_{z2} \xrightarrow{del_2} I_{z2}$  has 0.0195 amplitude. The total amplitude of this group is -  
 149 0.0574702.

150 The third group contains 24 paths where each of the paths contains two of the operators  $2I_{x1}I_{y2}$   
 151 or  $2I_{y1}I_{x2}$ . For example, the path  $I_{z1} \xrightarrow{\pi_x} 2I_{y1}I_{x2} \xrightarrow{del_1} 2I_{y1}I_{x2} \xrightarrow{\pi_y} I_{z2} \xrightarrow{del_2} I_{z2}$  has 0.0393 amplitude, whereas  
 152 the path  $I_{z1} \xrightarrow{\pi_x} 2I_{y1}I_{x2} \xrightarrow{del_1} I_{z2} \xrightarrow{\pi_y} 2I_{y1}I_{x2} \xrightarrow{del_2} I_{z2}$  has -0.000179 amplitude. The total amplitude of this  
 153 group is 0.13445302.

154 The fourth group contains eight paths where each of the paths contains three instances of the  
 155 operators  $2I_{x1}I_{y2}$ ,  $2I_{y1}I_{x2}$ . For example, the path  $I_{z1} \xrightarrow{\pi_x} 2I_{y1}I_{x2} \xrightarrow{del_1} 2I_{y1}I_{x2} \xrightarrow{\pi_y} 2I_{y1}I_{x2} \xrightarrow{del_2} I_{z2}$  has -  
 156 0.0393 amplitude, whereas the path  $I_{z1} \xrightarrow{\pi_x} 2I_{x1}I_{y2} \xrightarrow{del_1} 2I_{x1}I_{y2} \xrightarrow{\pi_y} 2I_{x1}I_{y2} \xrightarrow{del_2} I_{z2}$  has 0.0197 amplitude.  
 157 The total amplitude of this group is -0.0191567.

158 The total amplitude of all four groups at the time point  $2T_R$  is 0.097, which is the same as for the  
 159 heteronuclear  $IS$  spin system.

## 160 **RFDR Phase Cycling**

161 In this section we show that under the specific conditions of two spins and no chemical shift  
 162 offsets, there is zero RFDR transfer between operators  $I_{z1}$  and  $I_{z2}$  at  $t_{mix}=nT_R$  ( $n=1,2,3,\dots$ ) when  $XX$  phase  
 163 cycling is used. The measured operator at this time is described with the Eq.:

$$\langle I_{z2} \rangle(T_R) = Tr\{I_{z2}U(T_R)I_{z1}U^{-1}(T_R)\}. \quad \text{Eq. (S2)}$$

164 We take into account the dipolar interaction as well as the rf-field during the  $\pi$ -pulse. Then the unitary  
165 operator,  $U(T_R)$  is written as follow:

$$166 \quad U(T_R) = U_2U_1 \quad \text{Eq. (S3)}$$

$$167 \quad U_1 = \hat{T} \exp \left\{ \int_0^{t_p} dt [\omega_{D,12}(t)(3I_{z1}I_{z2} - \bar{I}_1\bar{I}_2) + \omega_{rf}(I_{x1} + I_{x2})] \right\}, \quad \text{Eq. (S3a)}$$

$$168 \quad U_2 = \hat{T} \exp \left\{ \int_{t_p}^{T_R} dt \omega_{D,12}(t)(3I_{z1}I_{z2} - \bar{I}_1\bar{I}_2) \right\}. \quad \text{Eq. (S3b)}$$

169 where  $\hat{T}$  is a Dyson operator and  $\omega_{D,12}(t)$  is a periodic dipolar time dependent function(Olejniczak et al.,  
170 1984) between spins  $I_1$  and  $I_2$ . Firstly, we can simplify Eq. S3 omitting the scalar product,  $\bar{I}_1\bar{I}_2$ , since it  
171 commutes with other parts of the Hamiltonian:

$$[\bar{I}_1\bar{I}_2, I_{z1}I_{z2}] = [\bar{I}_1\bar{I}_2, I_{x1} + I_{x2}] = 0, \quad \text{Eq. (S4)}$$

172 and the dipolar function is periodic  $-\int_0^{T_R} dt \omega_{D,12}(t)\bar{I}_1\bar{I}_2 = 0$ . Eq. S3a-b can be written as follow:

$$173 \quad U_1 = \hat{T} \exp \left\{ \int_0^{t_p} dt [\omega_{D,12}(t)3I_{z1}I_{z2} + \omega_{rf}(I_{x1} + I_{x2})] \right\}, \quad \text{Eq. (S5a)}$$

$$174 \quad U_2 = \hat{T} \exp \left\{ \int_{t_p}^{T_R} dt \omega_{D,12}(t)3I_{z1}I_{z2} \right\}. \quad \text{Eq. (S5b)}$$

175 The next step is the rotation of all the operators by  $90^\circ$  around axis -y:

$$I_{z1}, I_{z2}, I_{z1}I_{z2}, (I_{x1} + I_{x2}) \xrightarrow{90-y} -I_{x1}, -I_{x2}, I_{x1}I_{x2}, (I_{z1} + I_{z2}). \quad \text{Eq. (S6)}$$

176 Substituting Eq. (S6) into Eqs. S2 and Eq. (S5a-b), the modified Eq. (S2) is:

$$\langle I_{z2} \rangle(T_R) = Tr\{I_{x2}U_2U_1I_{x1}U_1^{-1}U_2^{-1}\}, \quad \text{Eq. (S7)}$$

177 whereas the modified Eq. (S5a-b) is:

$$178 \quad U_1 = \hat{T} \exp \left\{ \int_0^{t_p} dt [\omega_{D,12}(t)3I_{x1}I_{x2} + \omega_{rf}(I_{z1} + I_{z2})] \right\} \quad \text{Eq. (S8a)}$$

179  $U_2 = \hat{T} \exp \left\{ \int_{t_p}^{T_R} dt \omega_{D,12}(t) 3I_{x1} I_{x2} \right\}, \quad \text{Eq. (S8b)}$

180 The operators in Eq. (S8a-b) can be rewritten with fictitious spin 1/2 operator formalism(Vega, 1978):

$$\begin{aligned} 2I_{x1} I_{x2} &= I_x^{(2,3)} + I_x^{(1,4)}, \\ (I_{z1} + I_{z2}) &= 2I_z^{(1,4)}. \end{aligned} \quad \text{Eq. (S9)}$$

181 Therefore, Eqs. (S8a-b) can be written as follow:

182  $U_1 = \hat{T} \exp \left\{ \int_0^{t_p} dt \left[ \omega_{D,12}(t) 3 \left( I_x^{(1,4)} + I_x^{(2,3)} \right) + \omega_{rf} 2I_z^{(1,4)} \right] \right\} \quad \text{Eq. (S10a)}$

183  $U_2 = \hat{T} \exp \left\{ \int_{t_p}^{T_R} dt \omega_{D,12}(t) 3 \left( I_x^{(1,4)} + I_x^{(2,3)} \right) \right\}. \quad \text{Eq. (S10b)}$

184 Since the operator  $I_x^{(2,3)}$  commutes with other operators and the dipolar function is periodic –

185  $\int_0^{T_R} dt \omega_{D,12}(t) I_x^{(2,3)} = 0$  – the Eqs. (S7) and (S10a-b) can be rewritten as:

186  $\langle I_{z2} \rangle (T_R) = \text{Tr} \left\{ I_{x2} U_2^{(1,4)} U_1^{(1,4)} I_{x1} \left( U_2^{(1,4)} U_1^{(1,4)} \right)^{-1} \right\}, \quad \text{Eq. (S11)}$

187  $U_1^{(1,4)} = \hat{T} \exp \left\{ \int_0^{t_p} dt \left[ \omega_{D,12}(t) 3I_x^{(1,4)} + \omega_{rf} 2I_z^{(1,4)} \right] \right\}, \quad \text{Eq. (S12a)}$

188  $U_2^{(1,4)} = \hat{T} \exp \left\{ \int_{t_p}^{T_R} dt \omega_{D,12}(t) 3I_x^{(1,4)} \right\}. \quad \text{Eq. (S12b)}$

189 On the basis of the fictitious spin 1/2 operator formalism(Vega, 1978), the next properties always hold:

$$\begin{aligned} 2I_{xj} I_x^{(1,4)} 2I_{xj} &= I_x^{(2,3)}, \\ 2I_{xj} I_z^{(1,4)} 2I_{xj} &= -I_z^{(2,3)}, \quad j = 1, 2. \end{aligned} \quad \text{Eq. (S13)}$$

190 On the basis of these properties Eqs. (S11) and (S12) are:

191  $\langle I_{z2} \rangle (T_R) = \text{Tr} \left\{ I_{x2} I_{x1} \check{U}_2^{(2,3)} \check{U}_1^{(2,3)} \left( U_2^{(1,4)} U_1^{(1,4)} \right)^{-1} \right\}, \quad \text{Eq. (S14)}$

192  $\check{U}_1^{(2,3)} = \hat{T} \exp \left\{ \int_0^{t_p} dt \left[ \omega_{D,12}(t) 3I_x^{(2,3)} - \omega_{rf} 2I_z^{(2,3)} \right] \right\}, \quad \text{Eq. (S15a)}$

193  $\check{U}_2^{(2,3)} = \hat{T} \exp \left\{ \int_{t_p}^{T_R} dt \omega_{D,12}(t) 3I_x^{(2,3)} \right\}. \quad \text{Eq. (S15b)}$

194 On the basis of Eq. (S9) the product of  $I_{x2}I_{x1}$  can be rewritten and therefore Eq. (S14) is:

$$\begin{aligned}
 \langle I_{zz} \rangle (T_R) &= 0.5 \text{Tr} \left\{ \left( I_x^{(2,3)} + I_x^{(1,4)} \right) \left( \tilde{U}_2^{(2,3)} \tilde{U}_1^{(2,3)} \right) \left( U_2^{(1,4)} U_1^{(1,4)} \right)^{-1} \right\} = \\
 &= 0.5 \text{Tr} \left\{ I_x^{(2,3)} \tilde{U}_2^{(2,3)} \tilde{U}_1^{(2,3)} \right\} + 0.5 \text{Tr} \left\{ I_x^{(1,4)} \left( U_2^{(1,4)} U_1^{(1,4)} \right)^{-1} \right\}. \quad \text{Eq. (S16)}
 \end{aligned}$$

197 The next step is to use the properties of fictitious spin  $\frac{1}{2}$  operator formalism (Eq. S13) to arrive at:

$$\langle I_{zz} \rangle (T_R) = 0.5 \text{Tr} \left\{ I_x^{(2,3)} \tilde{U}_2^{(2,3)} \tilde{U}_1^{(2,3)} \right\} + 0.5 \text{Tr} \left\{ I_x^{(2,3)} \left( \tilde{U}_2^{(2,3)} \tilde{U}_1^{(2,3)} \right)^{-1} \right\}. \quad \text{Eq. (S17)}$$

199 The last step is to use the property:

$$\begin{aligned}
 -2I_y^{(2,3)} I_x^{(2,3)} 2I_y^{(2,3)} &= I_x^{(2,3)}, \\
 -2I_y^{(2,3)} I_z^{(2,3)} 2I_y^{(2,3)} &= I_z^{(2,3)}.
 \end{aligned} \quad \text{Eq. (S18)}$$

200 Substituting Eq. (S18) into Eq. (S115a-b), then the modified Eq. (S15a-b) into Eq. (S17) and considering

201 that  $2I_y^{(2,3)} 2I_y^{(2,3)} = 1^{(2,3)}$  and  $\left[ I_x^{(2,3)}, \tilde{U}_2^{(2,3)} \right] = 0$ , the transferred signal is:

$$\langle I_{zz} \rangle (T_R) = -0.5 \text{Tr} \left\{ I_x^{(2,3)} \left( \tilde{U}_2^{(2,3)} \tilde{U}_1^{(2,3)} \right)^{-1} \right\} + 0.5 \text{Tr} \left\{ I_x^{(2,3)} \left( \tilde{U}_2^{(2,3)} \tilde{U}_1^{(2,3)} \right)^{-1} \right\} = 0. \quad \text{Eq. (S19)}$$

203 Since the transferred signal is zero at the mixing time of one rotor period, it is always zero at integer  
 204 multiples of rotor periods.
