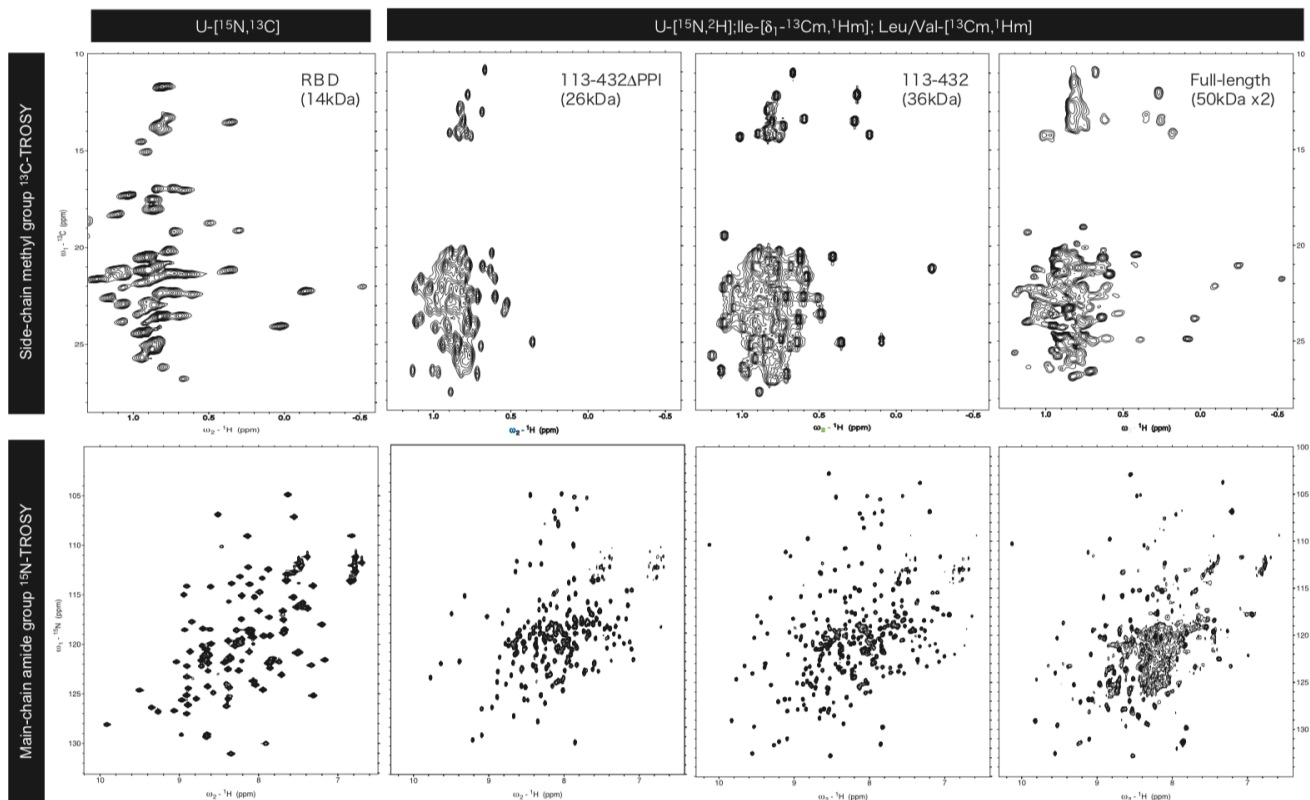

Figure S1. Divide-and-conquer strategy for NMR assignments of TF. The side-chain methyl ^{13}C - ^1H correlation spectra are shown on the top panels. The backbone amide ^{15}N - ^1H correlation spectra are shown on the bottom panels. Except for RBD, which was not deuterated and selectively methyl-labeled, all other constructs, namely SBD (113-432 Δ PPI), TF113-432 and full-length TF were perdeuterated and selectively protonated and ^{13}C labeled in the methyl groups of isoleucine $\delta 1$, leucine, and valine.

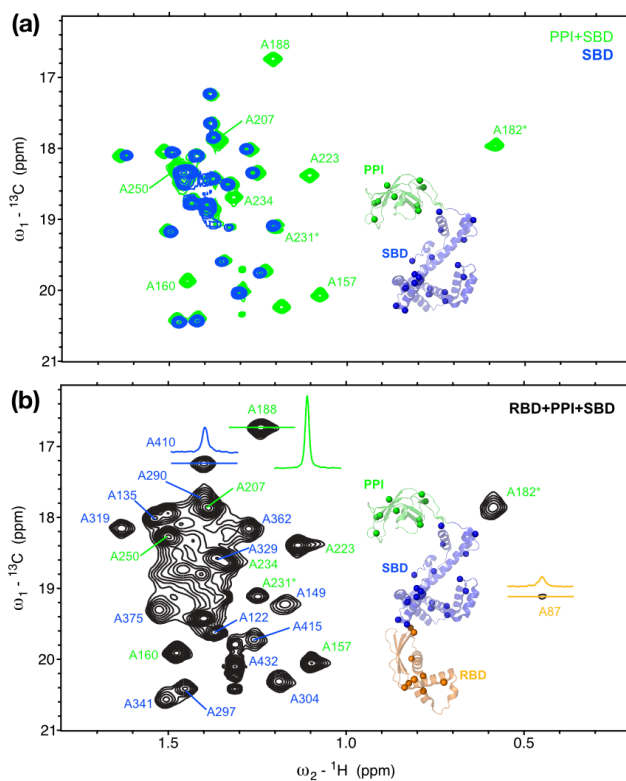

Figure S2. Alanine methyl NMR spectral analyses of TF variants. (a) Superposition of the methyl ^{13}C - ^1H correlation spectra of SBD (blue) and TF₁₁₃₋₄₃₂ (green) with selected crosspeaks originated from PPI labeled with their residue identities. (b) Methyl ^{13}C - ^1H correlation spectra of full-length TF with resolved crosspeaks labeled with the corresponding residue identities. The proton lineshapes of selected resonances are shown for RBD, PPI and SBD as indicated by the horizontal lines. Insets: cartoon representations of TF₁₁₃₋₄₃₂ (a) and full-length TF (b) with RBD, PPI and SBD colored in orange, green and blue, respectively. The C β atoms of the selectively protonated and ^{13}C labeled alanine side-chains are shown in spheres. All constructs were perdeuterated with selective protonation and ^{13}C labeling at the alanine C β positions.
