**Abstract.** Analytical expressions for the description of the time evolution of spin systems beyond the product-operator formalism (POF) can be obtained if a low-dimensional subspace of the Liouville space has been found. The latter can be established by a procedure that consists of a repeated application of the commutator of the Hamiltonian with the density operator. This iteration continues as long as the result of such a commutator operation contains a term that is linearly independent of all the operators appearing in the previous commutator operations. The coefficients of the resulting system of commutator relations can be immediately inserted into the generic propagation formulae given in this article if the system contains two, three or four equations. In cases not satisfying the validity conditions of any of these propagation formulae, the coefficients are used as intermediate steps to obtain both the Liouvillian and propagator matrices of the system. Several application examples are given where an analytical equation can be obtained for the description of the time evolution of small spin systems under the influence of two or more interactions.

## 1 Introduction

Considerable progress has been made in predicting the time evolution of spin systems. Numerical calculations or simulations are possible in large systems of coupled spins (Kuprov et al., 2007), and the evolution during an arbitrarily long sequence of pulses can be simulated with the help of software (Veshtort and Griffin, 2006; Bak et al., 2000; Hogben et al., 2011), including the effect of thermal motion.

However, there may be situations where the analytical representation of the time evolution is advantageous, providing more physical intuition than numerical results. In many cases, the product-operator formalism (POF) (Slichter, 1987; Sorensen et al., 1983; Packer and Wright, 1983; Wang, 1986) has been used for this purpose. This is a rather intuitive scheme, where the states of the spin system are represented by spin operators. Such a tool can be very useful for doing short calculations without access to fundamental quantum mechanics or without a simulation program. For demonstrations in discussions and lectures, e.g. on the effects of pulse sequences like INEPT, HSQC (vandeVen and Hilbers, 1983), an illustrative explanation can be given here. As an example, consider the POF description of the propagation of transversal magnetization of spin  $I = 1/2$  which is scalarly coupled to another spin  $S = 1/2$  (coupling constant  $J$ ):

$$\hat{I}_z \xrightarrow{2\pi J \hat{I}_z \hat{S}_z \cdot t} \hat{I}_z \cos \pi J t + 2 \hat{I}_y \hat{S}_z \sin \pi J t \quad (1)$$

- 25 This means that the spin system oscillates between two states characterized by the operators  $\hat{I}_z$  and  $2\hat{I}_z\hat{S}_z$ . Thus, the evolution takes place in a two-dimensional subspace of the total operator space. In contrast, to describe a system with two spins 1/2, we need a  $4 \times 4$  density matrix. This means that the Liouville-von Neumann equation is a system of 16 scalar differential equations for each of the matrix elements. But obviously it is possible in this case to reduce the 16D problem to the 2D one described by equation (1).
- 30 The question arises: Are there other situations where dimensionality reduction is possible? For example: Evolution of a spin system under dipol-dipol interaction and rf irradiation, cross polarization regarding the finiteness of rf power, i.e.

$$\begin{array}{l} \hat{I}_z \xrightarrow{\text{dipol-dipol interaction + rf irradiation}} ? \\ \hat{I}_x \xrightarrow{\text{cross polarization under finite rf power}} ? \end{array}$$

- or others? For numerical calculations, any reduction in dimensionality leads to a reduction in computational time, but for enabling analytical calculations, which is the goal here, it may be essential. The aims of this paper are (i) to introduce a
- 35 procedure for reducing the dimension of the problem, (ii) to show examples of the application of this procedure to obtain analytical equations, and (iii) to show the resulting generic propagation rules as templates for the cases that the problem could be reduced to a 2D, 3D, or 4D problem.
- In section 2, the mathematical background is investigated, which makes it possible to reduce the dimension to the value 2 in cases where the POF is applicable. The results of this consideration are applied to more complex structures in section 3.
- 40 Finally, in section 4, some template formulae are given together with examples for cases where a reduction to 3D, 4D, 5D and 6D problems is possible.

## 2 Dimension reduction through POF

### 2.1 Condition for validity: Commutator relations

- As shown in the references cited above, the generic scheme of the POF is as follows: The time evolution can be predicted by
- 45 the propagation rules

$$\begin{array}{l} \hat{A} \xrightarrow{\hat{H} \cdot t} \hat{A} \cos \lambda t + \hat{B} \sin \lambda t \quad ; \\ \hat{B} \xrightarrow{\hat{H} \cdot t} \hat{B} \cos \lambda t - \hat{A} \sin \lambda t \end{array} \quad (2)$$

if and only if

$$\begin{array}{l} [\hat{H}, \hat{A}] = i\lambda\hat{B} \quad \text{and} \\ [\hat{H}, \hat{B}] = -i\lambda\hat{A} \end{array} \quad (3)$$

where  $[\hat{A}, \hat{B}] \equiv \hat{A}\hat{B} - \hat{B}\hat{A}$  denotes the commutator between the operators  $\hat{A}$  and  $\hat{B}$ . That is, Eq. (2) describes the motion of  
 50 the density operator in a two-dimensional subspace of the total Liouville space of the current spin system independent of the  
 dimension of the latter.

However, condition (3) cannot be fulfilled if more than one interaction has to be considered. This applies, for example, to an rf  
 irradiation with strength  $\omega_1$  on an ensemble of spins  $I = 1/2$  which are coupled to another spin  $S = 1/2$  (coupling frequency  
 $D_{IS}$ ). This situation can be described by the Hamiltonian  $\hat{H} = -2D_{IS}\hat{I}_z\hat{S}_z - \omega_1\hat{I}_x$  and an initial state  $\rho_0 = \hat{I}_z$ . The double  
 55 calculation of the commutator of the Hamiltonian with  $\hat{I}_z$  does not only result in  $\hat{I}_z$ , but an additional term appears. In this  
 case, after the third application of this commutator operation, the result will contain only the operators already used:

$$\begin{aligned} [\hat{H}, \hat{I}_z] &= i\omega_1 \hat{I}_y \\ [\hat{H}, \hat{I}_y] &= -iD_{IS} \cdot 2\hat{I}_x\hat{S}_z - i\omega_1 \hat{I}_z \\ [\hat{H}, 2\hat{I}_x\hat{S}_z] &= iD_{IS} \cdot \hat{I}_y \end{aligned} \quad (4)$$

The connection between the commutator equations (3) and the propagation formulae (2) becomes much clearer if we reformu-  
 late both sets of equations in matrix form:

$$60 \begin{pmatrix} \hat{A} \\ \hat{B} \end{pmatrix} \xrightarrow{\hat{H} \cdot t} \begin{pmatrix} \cos \lambda t & \sin \lambda t \\ -\sin \lambda t & \cos \lambda t \end{pmatrix} \begin{pmatrix} \hat{A} \\ \hat{B} \end{pmatrix} \quad (5)$$

if and only if

$$\begin{pmatrix} [\hat{H}, \hat{A}] \\ [\hat{H}, \hat{B}] \end{pmatrix} = \begin{pmatrix} 0 & i\lambda \\ -i\lambda & 0 \end{pmatrix} \begin{pmatrix} \hat{A} \\ \hat{B} \end{pmatrix} \quad (6)$$

For this analysis, it is important to note that the first of the  $2 \times 2$  matrices in Eq. (5) is the exponential of the second matrix  
 multiplied by  $-it$  (see SI, section 2):

$$65 \begin{pmatrix} \cos \lambda t & \sin \lambda t \\ -\sin \lambda t & \cos \lambda t \end{pmatrix} = \exp \begin{pmatrix} 0 & \lambda t \\ -\lambda t & 0 \end{pmatrix} \quad (7)$$

Obviously, for this case, it is possible to take a particular parameter ( $\lambda$ ) of a system of commutator equations and insert it into  
 the template equation (2), which is formed as a set of two propagation formulae. Then the following questions arise:

1. Is it possible to apply this procedure to more complex cases, such as that of Eq. (4)?
2. To what dimension can we reduce a given problem?
- 70 3. Are there any template propagation formulae for the case that a reduction to a 3D or a 4D case was possible?

As a final remark in this subsection, we note that we have performed these considerations in the operator space (Liouville  
 space). This seems advantageous because it is the natural way to treat this topic. We describe states in terms of operators rather  
 than by wave functions, see above. Some properties of the Liouville space that are important for the further work here are listed  
 in the following subsection.

## 75 2.2 Properties of the Liouville space that are important in this article

In some papers, the space of the wave functions is denoted as Hilbert space in order to have a contrast to the Liouville space. However, this does not seem appropriate since the space of linear operators also satisfies the conditions to be a Hilbert space (Jordan, 2005).

80 – Definition of the scalar product of two operators  $\hat{A}$  und  $\hat{B}$ :  $(\hat{A}, \hat{B}) := \text{Tr}(\mathbf{A}^\dagger \cdot \mathbf{B})$  where  $\mathbf{A}$  and  $\mathbf{B}$  are the matrix representations of  $\hat{A}$  and  $\hat{B}$  in the wave-function space, and the superscript  $\dagger$  means the Hermitian conjugated of the corresponding matrix.

– Two operators  $\hat{A}$  and  $\hat{B}$  are said to be orthogonal if their scalar product is zero:  $\hat{A} \perp \hat{B} \Leftrightarrow (\hat{A}, \hat{B}) = 0$ .

85 – The Euclidean norm of an operator is defined as the square root of the scalar product of the operator with itself:  $\|\hat{A}\| = \sqrt{(\hat{A}, \hat{A})} = \sqrt{\text{Tr}(\mathbf{A}^T \cdot \mathbf{A})}$ . For the sake of brevity, the term "norm" is used throughout this paper to refer to the Euclidean norm. Rules for estimating the norm values for some of the operators used in this article are given in the Appendix. The norm of an operator is invariant with respect to a unitary transformation, but it can change if the relevant space is changed (e.g., addition or subtraction of a spin). Therefore, the table in the appendix contains different norm equations for the same operator but in different spaces;

90 – Each operator of this space can be expanded into a series of basis operators. In particular, for the density operator  $\rho$  we have

$$\hat{\rho} = \rho_1 \hat{u}_1 + \dots + \rho_d \hat{u}_d = \mathbf{u}^T \cdot \boldsymbol{\rho} \quad (8)$$

where  $d$  is the dimension of the particular Liouville space,  $\boldsymbol{\rho}$  is a column matrix which contains the expansion coefficients  $\rho_i$  ( $i \in \{1..d\}$ ) of the density operator,  $\mathbf{u}$  is a column matrix the elements of which are the basis operators, and  $\mathbf{A}^T$  is the transpose of the matrix  $\mathbf{A}$ . If all basis operators are pairwise orthogonal, the  $\rho_i$  can be calculated as follows

95 
$$\rho_i = (\hat{\rho}, \hat{u}_i) / \|\hat{u}_i\| \quad (i \in \{1..d\}) \quad (9)$$

– Mappings between operators are described by superoperators; examples:

• Liouville superoperator (or simply “Liouvillian”) for forming the commutator with the Hamiltonian:  $\hat{L} : \hat{A} \mapsto [\hat{H}, \hat{A}]$ , written also as  $\hat{L}\hat{A} = [\hat{H}, \hat{A}]$ ;

100 • propagation superoperator (or simply “superpropagator”) for describing the time evolution:  $\hat{U} : \hat{\rho}(0) \mapsto \hat{\rho}(t)$ , written also as  $\hat{U}\hat{\rho}(0) = \hat{\rho}(t)$ .

– The time evolution of the density operator is governed by the Liouville-von Neumann equation. It is formulated in the Liouville space as:

$$\frac{d}{dt} \hat{\rho} = -i \hat{L} \hat{\rho} \quad (10)$$

If  $\hat{L}$  does not depend on time, the formal solution is

$$105 \quad \hat{\rho}(t) = \hat{U}(t)\hat{\rho}(0) \quad \text{with} \quad \hat{U}(t) = \exp\left(-i\hat{L}t\right) \quad (11)$$

Here we find a similarity to the matrix formulation of the POF (Eqs. (5) to (7)). In fact, the coefficient matrix of the system of commutator equations is the transposition of the Liouvillian matrix, and the coefficient matrix of the POF (Eqn. (5)) is the transposition of the superpropagator. This is proved in the SI.

– The norm of the density matrix is time invariant. This can be proven by multiplying the Liouville-vonNeumann equation  
 110 (10) scalarly with  $\hat{\rho}$ :

$$\left(\hat{\rho} \cdot \frac{d}{dt}\hat{\rho}\right) = \frac{1}{2} \frac{d}{dt} (\hat{\rho} \cdot \hat{\rho}) = -i (\hat{\rho} \cdot \hat{L}\hat{\rho}) = 0 \quad (12)$$

because the scalar product of a hermitian operator ( $\hat{\rho}$ ) with its commutator to another hermitian operator ( $\hat{H}$ ) is zero, see SI.

The Liouville-space formulation of the objective of this article is: Find a subspace of the total Liouville space that contains  
 115 all possible states occurring in the current problem and that has the smallest possible dimension. An analogous procedure will not be possible in the wavefunction space, where the time evolution has to be calculated by  $\hat{U}(t)\hat{\rho}(0)\hat{U}^{-1}(t)$ . In the following section, commutator equations representing the action of the Liouvillian are established. Their coefficients are needed for further estimation of propagation formulae.

### 3 Procedure for finding propagation formulae

#### 120 3.1 Requirements for a suitable subspace

To be sure that a given subspace  $\mathbb{S}$  contains the whole evolution of a spin system, we have to check that the action of the propagator  $\hat{U}$  on each operator  $A$  of this subspace also results in an element of this subspace:

$$\forall \hat{A} \in \mathbb{S} \quad : \quad \hat{U} \hat{A} \in \mathbb{S} \quad (13)$$

A subspace with this property is said to be propagator invariant (Jordan, 2005). This is equivalent to the Liouvillian invariance  
 125 of the subspace, i.e.

$$\forall \hat{A} \in \mathbb{S} \quad : \quad \hat{L} \hat{A} \in \mathbb{S} \quad (14)$$

because the propagator is the sum of repeated  $\hat{L}$  actions:

$$\hat{U} \hat{A} = \exp\left(-i\hat{L}t\right) \hat{A} = \sum_{n=0}^{\infty} \frac{(-it)^n}{n!} \hat{L}^n \hat{A} \in \mathbb{S} \quad (15)$$

A sufficient condition for a subspace spanned by  $\hat{u}_1 \dots \hat{u}_N$  (Eq. (8)) to be Liouvillian invariant is the requirement that the  
 130 action of the Liouvillian on any of the  $\hat{u}_i$  also results in an element of that subspace, i.e.  $\hat{L}\hat{u}_i \in \mathbb{S} \quad \forall i \in \{1..N\}$ . A Liouvillian  
 invariant subspace which is of interest here should at least contain the initial density operator. Furthermore, all multiple actions  
 of the Liouvillian on the density operator must also result in elements of that subspace:  $\hat{L}^n \hat{\rho}(0) \in \mathbb{S} \quad \forall n \in \mathbb{N}$ .

In principle we can construct such a subspace as the set of all linear combinations of  $\hat{\rho}(0), \hat{L}\hat{\rho}(0), \hat{L}^2\hat{\rho}(0), \dots, \hat{L}^N\hat{\rho}(0)$ , where  
 135  $N$  is the largest number for which this operator set is linearly independent. This means that  $\hat{L}^{N+1}\hat{\rho}(0)$  can be represented as a  
 linear combination of all lower powers. Then all further applications of  $\hat{L}$  lead to operators which are also linearly dependent.  
 This procedure is reminiscent of the formation of Krylov subspaces in matrix spaces (Watkins, 2007). For further considerations  
 in this article, in particular the calculation of matrices, it is convenient to have basis operators that are pairwise orthogonal.  
 This can be achieved by combining the Krylov-like procedure with the Gram-Schmidt orthogonalization, which is analogous  
 to the Arnoldi procedure for matrix spaces (Watkins, 2007). The details of the procedure are presented in the next subsection.

### 140 3.2 First step: Creating a closed system of commutator equations

According to the result of the previous subsection, the application of the Liouvillian to the initial density operator is repeated  
 as long as the result contains a component that is linearly independent of all previous results. The action of the Liouvillian  
 consists in forming the commutator of the Hamiltonian with the considered operator.

Let us assume that the system under consideration is characterized by the Hamiltonian  $\hat{H}$  and the initial state density operator  
 145 by  $\hat{A}_1$ .

Evaluation of the first commutator:  $[\hat{H}, \hat{A}_1]$

If the result is zero, the state of the spin system is constant in time; see SI, examples 0D-1 and 0D-2. In the case that this  
 commutator does not vanish, it can be decomposed into a term which is proportional to  $\hat{A}_1$  and another term  $\hat{A}_{12}$  which is  
 orthogonal to the first one:

$$150 \quad [\hat{H}, \hat{A}_1] = \lambda_{11}\hat{A}_1 + \hat{A}_{12} \quad \text{with} \quad \hat{A}_{12} \perp \hat{A}_1 \quad (16)$$

The commutator of two Hermitian operators is always orthogonal to both, as proved in the SI. This means that for a Hermitian  
 $\hat{A}_1$ ,  $[\hat{H}, \hat{A}_1]$  cannot have a component that contains  $\hat{A}_1$  itself. This is different for non-Hermitian operators, see Example 1D-1  
 in the SI.

We replace  $\hat{A}_{12} \rightarrow \lambda_{12}\hat{A}_2$ , choosing the scalar  $\lambda_{12}$  so that  $\hat{A}_2$  has the same norm as  $\hat{A}_1$ . The corresponding table in the appendix  
 155 can be used to determine the norms of the operators.

Evaluation of the second commutator:  $[\hat{H}, \hat{A}_2]$

It will be decomposed as

$$[\hat{H}, \hat{A}_2] = \lambda_{21}\hat{A}_1 + \lambda_{22}\hat{A}_2 + \lambda_{23}\hat{A}_3 \quad (17)$$

with the condition that  $\hat{A}_3$  is orthogonal to both  $\hat{A}_1$  and  $\hat{A}_2$ . The coefficient  $\lambda_{23}$  is chosen so that  $\hat{A}_3$  has the same norm as  $\hat{A}_1$   
 160 and  $\hat{A}_2$ .

If  $\hat{A}_3 = 0$ , i.e.  $[\hat{H}, \hat{A}_2]$  is a linear combination of  $\hat{A}_1$ , the procedure is finished. Then we have a system of commutator equations like Eq. (3), i.e. the usual POF.

Evaluation of the  $n$ -th commutator:  $[\hat{H}, \hat{A}_n]$

Similarly, it will be expanded into a series of operators known from the previous commutator evaluations and a remainder:

$$165 \quad [\hat{H}, \hat{A}_n] = \lambda_{n1}\hat{A}_1 + \dots + \lambda_{n,n}\hat{A}_n + \lambda_{n,n+1}\hat{A}_{n+1} \quad (18)$$

with the condition that  $\hat{A}_{n+1}$  is orthogonal to all of the  $\hat{A}_k$  with  $k \in 1..n$ . Again, the coefficient  $\lambda_{n,n+1}$  is chosen so that  $\hat{A}_{n+1}$  has the same norm as the other operators of this set.

End of the procedure: If for a certain  $n = N$  the commutator is a linear combination of the previously determined  $\hat{A}_k$  without any remainder, the iteration is finished. The set of pairwise orthogonal operators  $\{\hat{A}_1.. \hat{A}_N\}$  spans a Liouvillian-invariant  
 170 subspace of the entire Liouville space. Its dimension is  $N$ .

Possible modification of the procedure: The remainder of any commutator evaluation can be written as the sum of two or more operators, all of which all must be orthogonal to the other operators. In some cases, this can simplify the coefficient matrix.

### 3.3 Second step: Liouvillian matrix

The result of the whole procedure is a system of equations like the following:

$$175 \quad \begin{pmatrix} [\hat{H}, \hat{A}_1] \\ [\hat{H}, \hat{A}_2] \\ [\hat{H}, \hat{A}_3] \\ \dots \\ [\hat{H}, \hat{A}_{N-2}] \\ [\hat{H}, \hat{A}_{N-1}] \\ [\hat{H}, \hat{A}_N] \end{pmatrix} \equiv \hat{L} \begin{pmatrix} \hat{A}_1 \\ \hat{A}_2 \\ \hat{A}_3 \\ \dots \\ \hat{A}_{N-2} \\ \hat{A}_{N-1} \\ \hat{A}_N \end{pmatrix} = \begin{pmatrix} \lambda_{11} & \lambda_{12} & 0 & \dots & 0 & 0 & 0 & 0 \\ \lambda_{21} & \lambda_{22} & \lambda_{23} & \dots & 0 & 0 & 0 & 0 \\ 0 & \lambda_{32} & \lambda_{33} & \dots & 0 & 0 & 0 & 0 \\ \dots & \dots & \dots & \dots & \dots & \dots & \dots & \dots \\ 0 & 0 & 0 & \dots & \lambda_{N-2,N-2} & \lambda_{N-2,N-1} & 0 & 0 \\ 0 & 0 & 0 & \dots & \lambda_{N-1,N-2} & \lambda_{N-1,N-1} & \lambda_{N-1,N} & 0 \\ 0 & 0 & 0 & \dots & 0 & \lambda_{N,N-1} & \lambda_{N,N} & 0 \end{pmatrix} \begin{pmatrix} \hat{A}_1 \\ \hat{A}_2 \\ \hat{A}_3 \\ \dots \\ \hat{A}_{N-2} \\ \hat{A}_{N-1} \\ \hat{A}_N \end{pmatrix} \quad (19)$$

As shown in the SI, the coefficient matrix is the transposition of the Liouvillian matrix. This system of equations implies that the action of the Liouvillian on any  $\hat{A}_i$  ( $i \in 1..N$ ) leads to a linear combination of the  $\hat{A}_i$ : In other words, the subspace spanned by the operators  $\hat{A}_1 \dots \hat{A}_n$  is both Liouvillian invariant and propagator invariant. The density operator, once being located in this subspace, will not leave it as long as the interaction does not vary. This explains why the POF can be successfully applied  
 180 as a 2D problem, even if the complete Liouville space has a much higher dimension.

The zeros in the upper triangle of the coefficient matrix result from the above: If the remainder of the  $n$ -th commutator is identified with only one new operator, then  $\lambda_{N,N+1}$  and  $\hat{A}_{N+1}$  are determined.  $\lambda_{N,N+2}, \dots$  and  $\hat{A}_{N+2}, \dots$  are still unknown at this step; the matrix elements to the right of them remain zero. In the case of the modified procedure mentioned above, the matrix structure in Eq. (19) changes. Then  $\lambda_{N,N+2}, \dots$  can also be nonzero. Due to the Hermiticity of the Liouvillian, i.e.  
 185  $L_{ij} = L_{ji}^*$ , the lower triangle matrix has the same pattern of zeros as the upper one. The coefficient matrix has a band structure for the unmodified version of the procedure.

When the basis operators are Hermitian, all elements are purely imaginary. This means that all elements of the main diagonal must be zero. However, if the basis contains non-Hermitian operators, the main diagonal will contain non-zero elements, but they must be real numbers.

### 190 3.4 Third step: Estimation of propagator matrix and propagation rules

In principle, the propagator matrix can be obtained by evaluating the matrix exponential according to Eq. (11):

$$\mathbf{U} = \exp(-i\mathbf{L}t) = \begin{pmatrix} U_{11} & U_{12} & \dots & U_{1N} \\ U_{21} & U_{22} & \dots & U_{2N} \\ \dots & \dots & \dots & \dots \\ U_{N1} & U_{N2} & \dots & U_{NN} \end{pmatrix} \quad (20)$$

$\mathbf{L}$  is a pure imaginary matrix for an hermitian operator basis. In this case,  $\mathbf{U}$  contains only real elements and is orthogonal. This means that the norms of all rows and all columns of this matrix are unity:

$$195 \sum_{i=1}^N U_{ij}^2 = \sum_{j=1}^N U_{ij}^2 = 1 \quad (21)$$

The propagation rules can be obtained from the elements of the propagator matrix:

$$\begin{aligned} \hat{A}_1 &\xrightarrow{\hat{H}\cdot t} \hat{A}_1 \cdot U_{11} + \hat{A}_2 \cdot U_{21} + \dots + \hat{A}_N \cdot U_{N1} \\ \hat{A}_2 &\xrightarrow{\hat{H}\cdot t} \hat{A}_1 \cdot U_{12} + \hat{A}_2 \cdot U_{22} + \dots + \hat{A}_N \cdot U_{N2} \\ &\dots \end{aligned} \quad (22)$$

However, it is not necessary to recompute the matrix exponential for each new situation. Instead, for low-dimensional subspaces, the generic propagation formulae shown in the next section can be used as a template. Here the elements of the Liouvillian matrix have to be inserted directly, without the need to perform the matrix exponentialization. This was done above for the POF example, where the constant  $\lambda$  resulting from the commutator equations could be used directly as the oscillation frequency.

## 4 Special cases

The situations in the examples shown below are characterized by different initial states and different Hamiltonians. The Hamiltonians are listed in Appendix B.

A detailed analytical consideration for each example can be found in the SI.

### 4.1 Reduction to a one-dimensional subspace

In this case, the commutator of the Hamiltonian with the density operator at  $t = 0$ , i.e.  $\hat{A}_1$ , is proportional to  $\hat{A}_1$  itself:

$$\left[ \hat{H}, \hat{A}_1 \right] = \lambda \hat{A}_1 \quad (23)$$

210 and occurs only if  $\hat{A}_1$  is non-Hermitian, e.g.  $\hat{A}_1 = \hat{I}_+ \equiv \hat{I}_x + i\hat{I}_y$  as used for the characterization of the complex FID, see Abragam (1961). Then the coefficient matrix consists of only one scalar  $\lambda$ . The propagator is also scalar:

$$\mathbf{U}_{1D} = e^{-i\lambda t} \quad (24)$$

and the corresponding propagation rule is

$$\hat{A}_1 \xrightarrow{\hat{H} t} \hat{A}_1 e^{-i\lambda t} \quad (25)$$

215 Example: Rotating frame, resonance offset  $\Delta\omega$ , complex transversal magnetization represented by  $\hat{I}_+$ :

$$\hat{I}_+ \xrightarrow{-\Delta\omega \hat{I}_z t} \hat{I}_+ e^{-i\Delta\omega t} \quad (26)$$

#### 4.2 Case of reduction to a 2D subspace

The corresponding equations are like Eqns. (3) and (6) and belong to the POF. The Liouvillian matrix and the propagator matrix are the transpositions of the matrices appearing above:

$$220 \quad \mathbf{L}_{2D} = \begin{pmatrix} 0 & -i\lambda \\ i\lambda & 0 \end{pmatrix}; \quad \mathbf{U}_{2D} = \exp(-i\mathbf{L}_{2D}t) = \begin{pmatrix} \cos \lambda t & -\sin \lambda t \\ \sin \lambda t & \cos \lambda t \end{pmatrix} \quad (27)$$

The propagation formulae are given by Eqn. (2). It describes an oscillatory behavior between the initial state and another state described by the commutator of the Hamiltonian with the operator corresponding to the density operator at the beginning.

In addition to the cases known from numerous POF applications, there are other situations that can be described as time evolution in a 2D subspace. All of them are well known; they are listed here for sake of completeness:

225 – Total transversal magnetization of an ensemble of isolated pairs of equal spins ( $I_1, I_2$ ); homonuclear dipolar interaction within the spin pairs:

$$\hat{I}_{1x} + \hat{I}_{2x} \xrightarrow{\hat{H}_{\Pi} t} (\hat{I}_{1x} + \hat{I}_{2x}) \cos \frac{3}{2} D_{\Pi} t - 2 (\hat{I}_{1z} \hat{I}_{2y} + \hat{I}_{1y} \hat{I}_{2z}) \sin \frac{3}{2} D_{\Pi} t \quad (28)$$

– Transversal  $I$  magnetization of an ensemble of isolated pairs of unlike spins ( $I, S$ ); heteronuclear dipolar interaction within the spin pairs:

$$230 \quad \hat{I}_x \xrightarrow{\hat{H}_{IS} t} \hat{I}_x \cos D_{IS} t - 2 \hat{I}_y \hat{S}_z \sin D_{IS} t \quad (29)$$

– Transversal magnetization of an ensemble of spins  $I = 1$  under quadrupolar interaction:

$$\hat{I}_x \xrightarrow{\hat{H}_Q t} \hat{I}_x \cos \omega_Q t + (\hat{I}_z \hat{I}_y + \hat{I}_y \hat{I}_z) \sin \omega_Q t \quad (30)$$

– Polarization exchange within pairs of antiparallel like spins:

$$\hat{I}_{1z} - \hat{I}_{2z} \xrightarrow{\hat{H}_{\Pi} t} (\hat{I}_{1z} - \hat{I}_{2z}) \cos D_{\Pi} t + 2 (\hat{I}_{1x} \hat{I}_{2y} - \hat{I}_{1y} \hat{I}_{2x}) \sin D_{\Pi} t \quad (31)$$

235 – Cross polarization within pairs of antiparallel unlike spins in the double-rotating frame (Hartmann and Hahn, 1962):

$$\hat{S}_z - \hat{I}_z \xrightarrow{\hat{H}_{\text{HH}} t} (\hat{S}_z - \hat{I}_z) \cos D_{\text{IS}} t + 2 (\hat{I}_x \hat{S}_y - \hat{I}_y \hat{S}_x) \sin D_{\text{IS}} t \quad (32)$$

The oscillation takes place in the first three examples between observable transversal magnetization and antiphase states, in the last two examples between longitudinal difference magnetization and zero and double quantum coherences.

### 4.3 Case of reduction to a 3D subspace

#### 240 4.3.1 Generic notation

The procedure described above reaches here the cancellation condition after three commutator equations of the kind

$$\begin{aligned} [\hat{H}, \hat{A}] &= ia\hat{B} \\ [\hat{H}, \hat{B}] &= -ia\hat{A} + ib\hat{C} \\ [\hat{H}, \hat{C}] &= -ib\hat{B} \end{aligned} \quad (33)$$

where  $a, b \in \mathbb{R}$ . In step 2, we estimate the Liouvillian matrix as

$$\mathbf{L}_{3\text{D}} = \begin{pmatrix} 0 & -ia & 0 \\ ia & 0 & -ib \\ 0 & ib & 0 \end{pmatrix} \quad (34)$$

245 and from that the matrix of the superpropagator:

$$\mathbf{U}_{3\text{D}} = \exp(-i\mathbf{L}_{3\text{D}}t) = \frac{1}{q^2} \begin{pmatrix} b^2 + a^2 \cos qt & -aq \sin qt & ab(1 - \cos qt) \\ aq \sin qt & q^2 \cos qt & -bq \sin qt \\ ab(1 - \cos qt) & bq \sin qt & a^2 + b^2 \cos qt \end{pmatrix} \quad (35)$$

with  $q^2 := a^2 + b^2$ . The orthogonality of  $\mathbf{U}_{3\text{D}}$ , i.e. the validity of Eqn. (21), can be verified immediately.

In step 3, the following propagation rules are obtained from the columns of  $\mathbf{U}_{3\text{D}}$ :

$$\hat{A} \xrightarrow{\hat{H} t} \hat{A} \cdot \frac{b^2 + a^2 \cos qt}{q^2} + \hat{B} \cdot \frac{a}{q} \sin qt + \hat{C} \cdot \frac{ab}{q^2} (1 - \cos qt) \quad (36)$$

$$250 \quad \hat{B} \xrightarrow{\hat{H} t} \hat{B} \cdot \cos qt + \hat{C} \cdot \frac{b}{q} \sin qt - \hat{A} \cdot \frac{a}{q} \sin qt \quad (37)$$

$$\hat{C} \xrightarrow{\hat{H} t} \hat{C} \cdot \frac{a^2 + b^2 \cos qt}{q^2} + \hat{A} \cdot \frac{ab}{q^2} (1 - \cos qt) - \hat{B} \cdot \frac{b}{q} \sin qt \quad (38)$$

This can be seen as an extension of the POF to three-dimensional problems.

If all basis operators are Hermitian, one of the eigenvalues of  $\mathbf{L}_{3\text{D}}$  is zero because of  $\det \mathbf{L}_{3\text{D}} = 0$ . Therefore, the solution of the Liouville-von Neumann equation may contain a non-zero constant beyond the oscillating terms. The propagator-matrix

**Figure 1.** Time evolution of the prefactor of  $\hat{A}$  in Eqn. (36) for different ratios  $b/a$ . The particular case  $b = 0$  leads to the 2D case; therefore, the corresponding curve is a pure oscillation around zero. With increasing  $b$ , the average levels of the related oscillations (dashed horizontal lines) increase whereas the corresponding amplitudes decrease.

255 element  $(U_{3D})_{11}$  contains the time evolution of the initial state  $\hat{A}$ . The constant term  $b^2/(a^2 + b^2)$  shows that the oscillations do not take place around zero as in the 2D case, but around another level. Moreover, its amplitude is reduced to  $a^2/(a^2 + b^2)$ , while the frequency increases the smaller the amplitude is, see Fig. 1.

There is one important special case:  $a = b$ . Here the propagation formulae are simplified to:

$$\hat{A} \xrightarrow{\hat{H}t} \hat{A} \cdot \cos^2 \frac{qt}{2} + \hat{B} \cdot \frac{1}{\sqrt{2}} \sin qt + \hat{C} \cdot \sin^2 \frac{qt}{2} \quad (39)$$

$$260 \quad \hat{B} \xrightarrow{\hat{H}t} \hat{B} \cdot \cos qt + \hat{C} \cdot \frac{1}{\sqrt{2}} \sin qt - \hat{A} \cdot \frac{1}{\sqrt{2}} \sin qt \quad (40)$$

$$\hat{C} \xrightarrow{\hat{H}t} \hat{C} \cdot \cos^2 \frac{qt}{2} + \hat{A} \cdot \sin^2 \frac{qt}{2} - \hat{B} \cdot \frac{1}{\sqrt{2}} \sin qt \quad (41)$$

This is applied in the description of cross polarization and polarization transfer, see the corresponding examples below.

#### 4.3.2 Group 1 of experiments leading to 3D subspaces: Magnetization initially aligned parallel to $B_0$

– Off-resonance nutation: rf irradiation with strength  $\omega_1$  on an ensemble of isolated spins under resonance offset  $\Delta\omega$ :

$$265 \quad \hat{I}_z \xrightarrow{(\hat{H}_R + \hat{H}_\Delta)t} \hat{I}_z \cdot \frac{\Delta\omega^2 + \omega_1^2 \cos qt}{q^2} + \hat{I}_y \cdot \frac{\omega_1}{q} \sin qt + \hat{I}_x \cdot \frac{\omega_1 \Delta\omega}{q^2} (1 - \cos qt) \quad (42)$$

with  $q^2 \rightarrow \omega_1^2 + \Delta\omega^2$ .

- Nutation and dipolar interaction: The observed spin  $I$ , which is heteronuclearly coupled to the spin  $S$ , is additionally irradiated with rf of the strength  $\omega_{1I}$ :

$$\hat{I}_z \xrightarrow{(\hat{H}_I + \hat{H}_{IS})t} \hat{I}_z \cdot \frac{D^2 + \omega_{1I}^2 \cos qt}{q^2} + \hat{I}_y \cdot \frac{\omega_{1I}}{q} \sin qt + 2\hat{I}_x \hat{S}_z \cdot \frac{\omega_{1I} D}{q^2} (1 - \cos qt) \quad (43)$$

270 with  $q^2 \rightarrow \omega_{1I}^2 + D^2$ .

(The case of *homonuclear* interaction under rf irradiation leads to a 4D problem, see below.)

The similarity of the two equations (42) and (43) is obvious. For  $\Delta\omega \rightarrow 0$  and  $D_{IS} \rightarrow 0$ , respectively, they merge into an equation describing a rotation in the  $yz$  plane. Both equations reflect the well-known fact that a total inversion of the magnetization with a single rectangular pulse is only possible if the offset or the coupling is zero. In addition, coupling and  
 275 resonance offset change both the pulse duration  $\tau_{\pi/2}$  required to reach maximum  $y$  magnetization and the pulse duration  $\tau_{\pi}$  required to reach zero  $y$  magnetization to shorter times:

$$\tau_{\pi/2} = \frac{\pi}{2\sqrt{\omega_{1I}^2 + C^2}}; \quad \tau_{\pi} = \frac{\pi}{\sqrt{\omega_{1I}^2 + C^2}} \quad (44)$$

with  $C \rightarrow \Delta\omega$  for the off-resonance nutation (Eqn. (42)) and  $C \rightarrow D_{IS}$  for the nutation under heteronuclear dipolar interaction.

### 4.3.3 Group 2 of experiments leading to 3D subspaces: FID under both rf irradiation and dipolar interaction

- 280 – Decoupling experiment: Ensemble of spin pairs  $\{IS\}$ ; heteronuclear dipolar interaction between  $I$  and  $S$ , rf irradiation on  $S$  channel with finite rf power of strength  $\omega_{1S}$ ; spins  $I$  are observed:

$$\hat{I}_x \xrightarrow{(\hat{H}_S + \hat{H}_{IS})t} \hat{I}_x \cdot \frac{\omega_{1S}^2 + D_{IS}^2 \cos qt}{q^2} - 2\hat{I}_y \hat{S}_z \cdot \frac{D_{IS}}{q} \sin qt - 2\hat{I}_x \hat{S}_z \cdot \frac{\omega_{1S} D_{IS}}{q^2} (1 - \cos qt) \quad (45)$$

with  $q^2 \rightarrow \omega_{1S}^2 + D_{IS}^2$ . For obtaining the corresponding equation for the  $J$  coupling, replace  $D_{IS}$  with  $-\pi J$ . This equation describes a *partial* exchange of polarization between  $x$  magnetization and two antiphase states.

285 The decoupling effect is explained as follows: The observable part of the density operator - the prefactor of  $\hat{I}_x$  - contains a constant part  $\omega_{1S}^2 / (\omega_{1S}^2 + D_{IS}^2)$  and an oscillating part with the amplitude  $\omega_{1S}^2 / (\omega_{1S}^2 + D_{IS}^2)$ . Such oscillations were observed for instance in DIPSHIFT experiments (Kurz et al., 2013). Powder averaging leads to a rather fast decay of the oscillation which gives a broad line (Pake doublet) after Fourier transformation, while the former gives a  $\delta$  line. With increasing rf strength  $\omega_{1S}$ , the prefactor of the broad peak decreases to zero for infinite rf power, while that of the  $\delta$  line  
 290 increases. The constant component is subject to relaxation damping and chemical-shift-caused oscillation on a longer time scale and produces a more or less narrow line.

- In-resonance spin locking and heteronuclear dipolar coupling:

$$\hat{I}_x \xrightarrow{(\hat{H}_I + \hat{H}_{IS})t} \hat{I}_x \cdot \frac{\omega_{1I}^2 + D_{IS}^2 \cos qt}{q^2} - 2\hat{I}_y \hat{S}_z \cdot \frac{D_{IS}}{q} \sin qt + 2\hat{I}_z \hat{S}_z \cdot \frac{\omega_{1I} D_{IS}}{q^2} (1 - \cos qt) \quad (46)$$

with  $q^2 \rightarrow \omega_{1I}^2 + D_{IS}^2$ . This oscillation frequency is indeed equal to that of the corresponding nutation experiment, see  
 295 equation (43).

- In-resonance spin locking and homonuclear dipolar coupling:

$$\hat{I}_{1x} + \hat{I}_{2x} \xrightarrow{(\hat{H}_{1x} + \hat{H}_{11})t} \left( \hat{I}_{1x} + \hat{I}_{2x} \right) \cdot \frac{4\omega_{11}^2 + \frac{9}{4}D_{11}^2 \cos qt}{q^2} - 2 \left( \hat{I}_{1y}\hat{I}_{2z} + \hat{I}_{1z}\hat{I}_{2y} \right) \cdot \frac{3D_{11}}{2q} \sin qt + 2 \left( \hat{I}_{1z}\hat{I}_{2z} - \hat{I}_{1y}\hat{I}_{2y} \right) \cdot \frac{3\omega_{11}D_{11}}{q^2} (1 - \cos qt) \quad (47)$$

$$\text{with } q^2 \rightarrow 4\omega_{11}^2 + \frac{9}{4}D_{11}^2.$$

Comments on the spinlock examples (Eqns. (46) and (47)):

- 300 – Analogous to the other 3D examples, the oscillation takes place around a level that increases with  $\omega_{11}$ . The latter corresponds to the spin-locked part of the transversal magnetization. At the same time, the amplitude of the oscillation is reduced.
- These oscillations are observed at the beginning of spin-lock experiments (Krushelnitsky et al., 2018, 2023) and have been described theoretically by Garroway (1979) and McArthur et al. (1969). Due to their orientation dependence, they
- 305 decay quite rapidly in a powder sample, but can be refocused in MAS experiments.
- The propagation formula (46) is related to the same Hamiltonian as formula (43). As a consequence, the oscillation frequencies are the same. However, the different initial states lead to different subspaces and thus to different propagation formulae.

#### 4.3.4 Group 3 of experiments leading to 3D subspaces: Polarization transfer

- 310 The rf field strengths are assumed to be much larger than the corresponding coupling frequencies. This situation is very similar to the polarization transfer treated as 2D case. The difference lies in the initial states. Instead of the antiparallel orientation above, here one spin of the pairs is polarized and the other is not. The initial states are now only described by  $\hat{I}_{1z}$  and  $\hat{S}_z$ , resp. Since these operators are not elements of the 2D subspaces of the polarization difference examples above, the motion now takes place in other subspaces, which turn out to be three-dimensional.

- 315 – Equal spins:

$$\hat{I}_{1z} \xrightarrow{\hat{H}_{11}t} \hat{I}_{1z} \cdot \cos^2 \left( \frac{D_{11}t}{2} \right) + \left( \hat{I}_{1x}\hat{I}_{2y} + \hat{I}_{1y}\hat{I}_{2x} \right) \cdot \sin D_{11}t + \hat{I}_{2z} \cdot \sin^2 \left( \frac{D_{11}t}{2} \right) \quad (48)$$

- Pair of unequal spins  $I, S$  under Hartmann-Hahn condition in the double-rotating frame:

$$\hat{S}_z \xrightarrow{\hat{H}_{HH}t} \hat{S}_z \cdot \cos^2 \left( \frac{D_{1S}t}{2} \right) + \left( \hat{I}_x\hat{S}_y + \hat{I}_y\hat{S}_x \right) \cdot \sin D_{1S}t + \hat{I}_z \cdot \sin^2 \left( \frac{D_{1S}t}{2} \right) \quad (49)$$

- Depolarization of  $I$  spins in an ensemble of spin triples  $\{I, S_1, S_2\}$  under Hartmann-Hahn condition in the DRKS; coupling frequencies for the  $I - S_1$  and the  $I - S_2$  interactions:  $D_1$  and  $D_2$ , respectively. The interaction between  $S_1$
- 320

**Figure 2.** Time evolution of the three prefactors in the propagation rules Eqns. (48) and (49).

and  $S_2$  is assumed to be zero, e.g. due to rf irradiation on the  $S$  channel under Lee-Goldburg condition.

$$\begin{aligned}
 \hat{I}_z &\xrightarrow{\hat{H}_{\text{HH2}} \cdot t} \hat{I}_z \cdot \cos^2\left(\frac{\sqrt{D_1^2 + D_2^2} t}{2}\right) \\
 &\quad - \frac{D_1 (\hat{I}_x \hat{S}_{1y} - \hat{I}_y \hat{S}_{1x}) + D_2 (\hat{I}_x \hat{S}_{2y} - \hat{I}_y \hat{S}_{2x})}{\sqrt{D_1^2 + D_2^2}} \sin \sqrt{D_1^2 + D_2^2} t \\
 &\quad + \frac{D_1^2 \hat{S}_{1z} + D_2^2 \hat{S}_{2z} - 4D_1 D_2 \hat{I}_z (\hat{S}_{1x} \hat{S}_{2x} + \hat{S}_{1y} \hat{S}_{2y})}{D_1^2 + D_2^2} \sin^2\left(\frac{\sqrt{D_1^2 + D_2^2} t}{2}\right)
 \end{aligned} \tag{50}$$

Comment on the third item: The oscillation frequency is the geometric sum of the individual frequencies. The oscillation takes place between the initial state and a mixture of observable and unobservable states.

325 Note the first two propagation rules of the third group: Additionally to the orthogonality relations (Eqn. (21)), the linear sum of the prefactors of the first and the third terms is 1. Both terms represent  $z$  magnetization. This condition reflects that the sum of the  $z$  polarizations is constant for CP as well as for PT. This is supported by the fact that  $\hat{I}_{1z} + \hat{I}_{2z}$  commutes with  $\hat{H}_{\text{II}}$  and  $\hat{I}_z + \hat{S}_z$  commutes with  $\hat{H}_{\text{HH}}$ . Fig. 2 shows the time evolution of the three prefactors in these propagation rules.

#### 4.3.5 Group 4 of 3D examples: Cross polarization, finite rf power, possible deviation from HH condition

330 – Considering the polarization difference in the rotating frame:

$$\begin{aligned} \hat{S}_x - \hat{I}_x \xrightarrow{(\hat{H}_{I_x} + \hat{H}_{S_x} + \hat{H}_{I_S})t} & \left( \hat{S}_x - \hat{I}_x \right) \cdot \frac{\omega_\Delta^2 + D_{IS}^2 \cos q_\Delta t}{q_\Delta^2} \\ & - 2 \left( \hat{I}_z \hat{S}_y - \hat{I}_y \hat{S}_z \right) \cdot \frac{D_{IS}}{q_\Delta} \sin q_\Delta t \\ & + 2 \left( \hat{I}_z \hat{S}_z + \hat{I}_y \hat{S}_y \right) \cdot \frac{\omega_\Delta D_{IS}}{q_\Delta^2} \sin^2 q_\Delta t \end{aligned} \quad (51)$$

with  $\omega_\Delta \rightarrow \omega_{IS} - \omega_{IH}$  and  $q_\Delta^2 \rightarrow D_{IS}^2 + \omega_\Delta^2$ .

Comments:

335 – The CP oscillation frequency is no longer  $D_{IS}$  as calculated for infinite rf power (see above), but  $\sqrt{D_{IS}^2 + (\omega_{IH} - \omega_{IS})^2}$  which increases with the difference of the two rf field strengths.

– Moreover, only the relative part  $D_{IS}^2/q_\Delta^2$  of the total magnetization participates in the oscillation, i.e. the greater the deviation from the Hartmann-Hahn condition, the lower the maximum transmitted polarization.

– Considering the polarization sum:

$$\begin{aligned} \hat{S}_x + \hat{I}_x \xrightarrow{(\hat{H}_{I_x} + \hat{H}_{S_x} + \hat{H}_{I_S})t} & \left( \hat{S}_x + \hat{I}_x \right) \cdot \frac{4\omega_\phi^2 + D_{IS}^2 \cos q_\phi t}{q_\phi^2} \\ & - 2 \left( \hat{I}_z \hat{S}_y + \hat{I}_y \hat{S}_z \right) \cdot \frac{D_{IS}}{q_\phi} \sin q_\phi t \\ & + 2 \left( \hat{I}_z \hat{S}_z - \hat{I}_y \hat{S}_y \right) \cdot \frac{2\omega_\phi D_{IS}}{q_\phi^2} \sin^2 q_\phi t \end{aligned} \quad (52)$$

340 with  $\omega_\phi \rightarrow (\omega_{IS} + \omega_{IH})/2$  and  $q_\phi^2 \rightarrow D_{IS}^2 + 4\omega_\phi^2$ .

Contrary to the relations obtained for infinite  $\omega_1$ , the sum of both polarizations also oscillates, the more the smaller the rf power. The amplitude of this oscillation decreases as  $\omega_\phi$  increases. This phenomenon is analogous to what happens with spin-lock and decoupling, see the corresponding examples above.

## 345 4.4 Case of reduction to a 4D subspace

### 4.4.1 Generic notation

This group of situations can be described by commutator relations of the kind

$$\begin{aligned} [\hat{H}, \hat{A}] &= ia\hat{B} \\ [\hat{H}, \hat{B}] &= -ia\hat{A} + ib\hat{C} \\ [\hat{H}, \hat{C}] &= -ib\hat{B} \mp ia\hat{D} \\ [\hat{H}, \hat{D}] &= \pm ia\hat{C} \end{aligned} \quad (53)$$

where  $\hat{A}$ ,  $\hat{B}$ ,  $\hat{C}$  and  $\hat{D}$  are pairwise orthogonal operators with equal norms. According to step 2, we obtain the Liouvillian  
 350 matrix from these rules as

$$\mathbf{L}_{3D} = \begin{pmatrix} 0 & -ia & 0 & 0 \\ ia & 0 & -ib & 0 \\ 0 & ib & 0 & \pm ia \\ 0 & 0 & \mp ia & 0 \end{pmatrix} \quad (54)$$

and the superpropagator matrix as

$$\mathbf{U}_{4D} = \frac{1}{2W} \begin{pmatrix} q_2 \cos q_1 t + q_1 \cos q_2 t & -a(\sin q_1 t + \sin q_2 t) & a(\cos q_1 t - \cos q_2 t) & \mp q_2 \sin q_1 t \pm q_1 \sin q_2 t \\ a(\sin q_1 t + \sin q_2 t) & q_1 \cos q_1 t + q_2 \cos q_2 t & q_2 \sin q_2 t - q_1 \sin q_1 t & \pm a(\cos q_2 t - \cos q_1 t) \\ a(\cos q_2 t - \cos q_1 t) & q_1 \sin q_1 t - q_2 \sin q_2 t & q_1 \cos q_1 t + q_2 \cos q_2 t & \mp a(\sin q_1 t + \sin q_2 t) \\ \pm q_2 \sin q_1 t \mp q_1 \sin q_2 t & \pm a(\cos q_2 t - \cos q_1 t) & \pm a(\sin q_1 t + \sin q_2 t) & q_2 \cos q_1 t + q_1 \cos q_2 t \end{pmatrix} \quad (55)$$

with the abbreviations  $W^2 := (a^2 + b^2)/4$  and  $q_{1;2} := W \mp b/2$ .

355 The propagation rule for the case where  $\hat{A}$  was the initial state can be read from the first column of  $\mathbf{U}_{4D}$  in Eq. (55):

$$\hat{A} \xrightarrow{\hat{H} \cdot t} \hat{A} \cdot \frac{q_2 \cos q_1 t + q_1 \cos q_2 t}{2W} + \hat{B} \cdot \frac{a(\sin q_1 t + \sin q_2 t)}{2W} + \hat{C} \cdot \frac{a(\cos q_2 t - \cos q_1 t)}{2W} \pm \hat{D} \cdot \frac{q_2 \sin q_1 t - q_1 \sin q_2 t}{2W} \quad (56)$$

In some cases, another form of this propagation formula may be appropriate for use, which is obtained from Eq. (56) by applying some trigonometric rules:

$$\hat{A} \xrightarrow{\hat{H} \cdot t} \hat{A} \cdot \left( \cos(Wt) \cos \frac{bt}{2} + \frac{b}{2W} \sin(Wt) \sin \frac{bt}{2} \right) + \hat{B} \cdot \frac{a}{W} \sin(Wt) \cos \frac{bt}{2} \quad (57)$$

$$360 \quad -\hat{C} \cdot \frac{a}{W} \sin(Wt) \sin \frac{bt}{2} \mp \hat{D} \cdot \left( \cos(Wt) \sin \frac{bt}{2} + \frac{b}{2W} \sin(Wt) \cos \frac{bt}{2} \right) \quad (58)$$

**Figure 3.** Connection between the two oscillation frequencies  $q_1$  and  $q_2$  in the 4D problem, example AB spin system with  $\Delta\nu = 3J$ .

#### 4.4.2 Examples

- AB spinsystem,  $J$  coupling; distance of the two lines:  $\Delta\nu := \Delta\omega/(2\pi)$ , the spectrometer frequency is assumed to be set at the midpoint between the two resonances:

$$\begin{aligned}
 \hat{I}_{1x} + \hat{I}_{2x} &\xrightarrow{2\pi J \hat{I}_{1z} \hat{I}_{2z} t} \left( \hat{I}_{1x} + \hat{I}_{2x} \right) \cdot \frac{q_2 \cos q_1 t + q_1 \cos q_2 t}{W} \\
 &+ \left( \hat{I}_{1y} - \hat{I}_{2y} \right) \cdot \frac{\Delta\omega \sin q_1 t + \sin q_2 t}{2W} \\
 &+ 2 \left( \hat{I}_{1z} \hat{I}_{2x} - \hat{I}_{1x} \hat{I}_{2z} \right) \cdot \frac{\Delta\omega \cos q_1 t - \cos q_2 t}{2W} \\
 &- 2 \left( \hat{I}_{1y} \hat{I}_{2z} + \hat{I}_{1z} \hat{I}_{2y} \right) \cdot \frac{q_1 \sin q_2 t - q_2 \sin q_1 t}{W}
 \end{aligned} \tag{59}$$

365 where  $W \rightarrow 2\pi\sqrt{J^2 + \Delta\nu^2}$  and  $q_{1,2} \rightarrow \pi(\sqrt{J^2 + \Delta\nu^2} \mp J)$ . The cosine terms contain two frequencies that give four  
 line positions  $\pm q_1$  and  $\pm q_2$  symmetrically around zero after complex Fourier transformation. The intensities are given by  
 the prefactors of the corresponding trigonometric functions. The lower frequency oscillation has the larger prefactor, what  
 reflects the roof effect. See for example Abragam (1961), chapter XI, section B. In this book, positions and intensities  
 are calculated from transition frequencies and probabilities for the transitions between the levels. Fig. 3 shows the  
 370 relationship between  $q_1$ ,  $q_2$  and the intensities and positions of the four lines of an AB spin system.

For the case  $\Delta\nu = 0$  the Hamiltonian commutes with the initial state with the consequence that the density operator  
 remains constant the Fourier transform of which is just a resonance at zero frequency.

**Figure 4.** Nutation curves for different ratios of rf field strength and coupling strength. For homonuclear dipolar coupling:  $D_{II}/\omega_1 =$  (a): 0, (b): 0.15; (c): 0.3; (d): 0.45; (e): 0.6; (f): 0.75; for quadrupolar coupling:  $\omega_Q/\omega_1 =$  (a): 0; (b): 0.2; (c): 0.4; (d) 0.6; (e): 0.8; (f): 1.

– rf irradiation onto homonuclearly coupled spins 1/2 which are initially in equilibrium (nutation):

$$\begin{aligned} \hat{I}_{1z} + \hat{I}_{2z} &\xrightarrow{(\hat{H}_{II} + \hat{H}_{IX})t} (\hat{I}_{1z} + \hat{I}_{2z}) \cdot \left( \cos Wt \cos \frac{3D_{II}}{4}t + \frac{3D_{II}}{4W} \sin Wt \sin \frac{3D_{II}}{4}t \right) \\ &+ (\hat{I}_{1y} + \hat{I}_{2y}) \cdot \frac{\omega_{II}}{W} \sin Wt \cos \frac{3D_{II}}{4}t \\ &- 2(\hat{I}_{1x}\hat{I}_{2z} + \hat{I}_{1z}\hat{I}_{2x}) \cdot \frac{\omega_{II}}{W} \sin Wt \cos \frac{3D_{II}}{4}t \\ &- 2(\hat{I}_{1y}\hat{I}_{2x} + \hat{I}_{1x}\hat{I}_{2y}) \cdot \left( \cos Wt \sin \frac{3D_{II}}{4}t - \frac{3D_{II}}{4W} \sin Wt \cos \frac{3D_{II}}{4}t \right) \end{aligned} \quad (60)$$

375 where  $W \rightarrow \sqrt{\omega_{II}^2 + \frac{9}{16}D_{II}^2}$ .

This propagation formula describes the effect of a limited power rf pulse on the equilibrium magnetization. The time evolution of the prefactor of  $\hat{I}_{1y} + \hat{I}_{2y}$  is shown in Fig. 4.

Comments on Eqn. (60):

- 380
- As the coupling frequency increases, so does the nutation frequency  $W$ . However, this oscillation is modulated by half of the dipolar frequency, see Fig. 4.
  - As a consequence, the  $\pi$  and  $\pi/2$  conditions for achieving maximum and zero y magnetization, respectively, are modified with respect to the coupling-free case. Similar to Equation (61), this results in

$$\tau_{\pi/2} = \frac{\pi}{2\sqrt{\omega_{II}^2 + \frac{9}{16}D_{II}^2}}; \quad \tau_{\pi} = \frac{\pi}{\sqrt{\omega_{II}^2 + \frac{9}{16}D_{II}^2}} \quad (61)$$

– Nutation under quadrupolar interaction, spin 1:

$$\hat{I}_z \xrightarrow{(\hat{H}_Q + \hat{H}_{1k}) \cdot t} \hat{I}_z \cdot \left( \cos \frac{Wt}{2} \cos \frac{\omega_Q t}{2} + \frac{\omega_Q t}{W} \sin \frac{Wt}{2} \sin \frac{\omega_Q t}{2} \right) + \hat{I}_y \cdot \frac{2\omega_1}{W} \sin \frac{Wt}{2} \sin \frac{\omega_Q t}{2} - \left( \hat{I}_x \hat{I}_z + \hat{I}_z \hat{I}_x \right) \cdot \frac{2\omega_1}{W} \sin \frac{Wt}{2} \sin \frac{\omega_Q t}{2} + \left( \hat{I}_y \hat{I}_x + \hat{I}_x \hat{I}_y \right) \cdot \left( \cos \frac{Wt}{2} \sin \frac{\omega_Q t}{2} + \frac{\omega_Q t}{W} \sin \frac{Wt}{2} \cos \frac{\omega_Q t}{2} \right) \quad (62)$$

with  $W \rightarrow \sqrt{4\omega_1^2 + \omega_Q^2}$ . This is consistent with the findings of Bloom et al. (1980) and Vega and Luz (1987). Again, the result is that nutation occurs faster than  $\omega_{1I}$  if there is an additional interaction.

#### 4.5 Example for a 5D subspace

We consider cross polarization under finite rf power, assuming that the Hartmann-Hahn condition is satisfied:  $\omega_{1I} = \omega_{1S} =: \omega_1$ . Other than in the corresponding 3D examples shown above, the initial state consists of a transversally polarized  $S$  spin and a depolarized  $I$  spin, i.e.  $\hat{\rho}(0) = \hat{S}_x$ :

$$\hat{S}_x \xrightarrow{(\hat{H}_{1k} + \hat{H}_{Sx} + \hat{H}_{IS}) \cdot t} \frac{1}{2} \left[ \left( \cos D_{IS} t + \frac{4\omega_1^2 + D_{IS}^2 \cos qt}{q^2} \right) \cdot \hat{S}_x - \left( \frac{D_{IS}}{q} \sin qt + \sin D_{IS} t \right) \cdot 2\hat{I}_z \hat{S}_y + 4 \frac{D_{IS} \omega_1}{q^2} (1 - \cos qt) \left( \hat{I}_z \hat{S}_z - \hat{I}_y \hat{S}_y \right) + \left( \frac{D_{IS}}{q} \sin qt - \sin D_{IS} t \right) \cdot 2\hat{I}_y \hat{S}_z + \left( -\cos D_{IS} t + \frac{4\omega_1^2 + D_{IS}^2 \cos qt}{q^2} \right) \cdot \hat{I}_x \right] \quad (63)$$

Eq. (63) describes the evolution of the magnetization of the initially polarized spin. That of the other spin evolves as given in Eq. (64):

$$\hat{I}_x \xrightarrow{(\hat{H}_{1k} + \hat{H}_{Sx} + \hat{H}_{IS}) \cdot t} \frac{1}{2} \left[ \hat{S}_x \cdot \left( -\cos D_{IS} t + \frac{4\omega_1^2 + D_{IS}^2 \cos qt}{q^2} \right) - \left( \frac{D_{IS}}{q} \sin qt - \sin D_{IS} t \right) \cdot 2\hat{I}_z \hat{S}_y + 4 \frac{D_{IS} \omega_1}{q^2} (1 - \cos qt) \left( \hat{I}_z \hat{S}_z - \hat{I}_y \hat{S}_y \right) - \left( \frac{D_{IS}}{q} \sin qt + \sin D_{IS} t \right) \cdot 2\hat{I}_y \hat{S}_z + \left( \cos D_{IS} t + \frac{4\omega_1^2 + D_{IS}^2 \cos qt}{q^2} \right) \cdot \hat{I}_x \right] \quad (64)$$

#### 4.6 Examples for a 6D subspace

– HH-CP experiment with finite rf power, deviation from the Hartmann-Hahn condition, the initial state consists of a transversally polarized  $S$  spin and a depolarized  $I$  spin, i.e.  $\hat{\rho}(0) = \hat{S}_x$ . Using the variables defined in subsection 4.3.5

**Figure 5.** Examples for cross-polarization buildup curves for the  $I$  spins in an ensemble of spin pairs  $I, S$  corresponding to Eqn. (65) with  $\omega_{\phi} = 3D_{IS}$ . The deviation  $\omega_{\Delta}$  from the Hartmann-Hahn condition is varied.

we obtain

$$\begin{aligned}
 \hat{S}_x &\xrightarrow{(\hat{H}_x + \hat{H}_{Sx} + \hat{H}_{IS}) \cdot t} \hat{S}_x \cdot \frac{1}{2} \left( \frac{\omega_{\Delta}^2 + D_{IS}^2 \cos q_{\Delta} t}{q_{\Delta}^2} + \frac{4\omega_{\phi}^2 + D_{IS}^2 \cos q_{\phi} t}{q_{\phi}^2} \right) \\
 &- \hat{I}_z \hat{S}_y \cdot D_{IS} \left( \frac{\sin q_{\Delta} t}{q_{\Delta}} + \frac{\sin q_{\phi} t}{q_{\phi}} \right) \\
 &+ 2\hat{I}_z \hat{S}_z D_{IS} \left[ \frac{\omega_{\Delta}}{2q_{\Delta}} (1 - \cos q_{\Delta} t) + \frac{\omega_{\phi}}{q_{\phi}} (1 - \cos q_{\phi} t) \right] \\
 &+ 2\hat{I}_y \hat{S}_y D_{IS} \left[ \frac{\omega_{\Delta}}{2q_{\Delta}} (1 - \cos q_{\Delta} t) - \frac{\omega_{\phi}}{q_{\phi}} (1 - \cos q_{\phi} t) \right] \\
 &+ \hat{I}_y \hat{S}_z \cdot D_{IS} \left( \frac{\sin q_{\Delta} t}{q_{\Delta}} - \frac{\sin q_{\phi} t}{q_{\phi}} \right) \\
 &+ \hat{I}_x \cdot \frac{1}{2} \left( \frac{4\omega_{\phi}^2 + D_{IS}^2 \cos q_{\phi} t}{q_{\phi}^2} - \frac{\omega_{\Delta}^2 + D_{IS}^2 \cos q_{\Delta} t}{q_{\Delta}^2} \right)
 \end{aligned} \tag{65}$$

400

Fig. 5 shows the build-up curve for the  $I$  magnetization for the case where it was initially unpolarized, and  $S$  was polarized. For zero deviation from the Hartmann-Hahn condition, the curve still looks similar to the squared sine derived for infinite rf power (Eq. (49)). Small deformations result from the fact that the rf power is finite. An increasing deviation from the Hartmann-Hahn condition leads to a strong loss of the polarization-transfer efficiency, in addition to further deviation from the ideal curve.

405

- HHCP of a  $I$  spin from two  $S$  spins: The Hamiltonian is the same as in 4.3.4, and we consider the problem in the double-rotating frame. In this example, however, we want to follow the time evolution of all three spins individually which could not be separated in the 3D example. The propagation rules for all three spins can be found in the SI. Here is the

propagation rule for the case that the system starts with polarized S spins, i.e.  $\hat{A} \rightarrow \hat{S}_{1z} + \hat{S}_{2z}$  and  $\hat{H} \rightarrow \hat{H}_{\text{HH2}}$ :

$$410 \quad \hat{S}_{1z} + \hat{S}_{2z} \xrightarrow{\hat{H}_{\text{HH2}} \cdot t} \hat{I}_z \cdot \sin^2 \frac{qt}{2} + (\hat{S}_{1z} + \hat{S}_{2z}) \cdot \frac{1 + \cos^2 \frac{qt}{2}}{2} + (\hat{S}_{1z} - \hat{S}_{2z}) \cdot \frac{D_2^2 - D_1^2}{2q^2} \sin^2 \frac{qt}{2} \\ + (\hat{I}_x \hat{S}_{1y} - \hat{I}_y \hat{S}_{1x}) \frac{D_1}{q} \sin qt + (\hat{I}_x \hat{S}_{2y} - \hat{I}_y \hat{S}_{2x}) \frac{D_2}{q} \sin qt - \hat{I}_z (\hat{S}_{1x} \hat{S}_{2x} - \hat{S}_{1y} \hat{S}_{2y}) \cdot 4 \frac{D_1 D_2}{q^2} \sin^2 \frac{qt}{2} \quad (66)$$

with  $q \rightarrow \sqrt{D_1^2 + D_2^2}$ . This propagation rule describes the oscillatory polarization exchange between the spin polarizations and three unobservable states on the one hand, and the oscillatory polarization transfer between the spins on the other hand, as it may happen for example in  $^{13}\text{CH}_2$  or in  $^{15}\text{NH}_2$  groups.

## 5 Conclusions

415 Repeated application of the commutator of the Hamiltonian with the initial density operator gives a system of operator equations, the coefficient matrix of which can be used to establish a propagation rule for the spin system. This has been demonstrated in this paper with some examples. A more detailed analysis shows that the commutator relations define subspaces which are both Liouvillian invariant and superpropagator invariant. Therefore, the density operator propagates in such a subspace without leaving it. If its dimension is small enough, analytical expressions for the propagation law can be obtained.

420 The relevant subspace for a given problem is determined by the Hamiltonian and by the initial state. If the operator characterizing the initial state changes, then the new subspace is the same as the previous one if and only if the new initial-state operator is an element of the previous subspace, otherwise the two subspaces have no intersection.

The set of problems can be divided into classes with respect to the dimension of the subspaces. Problems of the 2D class can be easily treated by propagation formulae similar to those of the well-known product-operator formalism. The propagation 425 formulae for the 3D and 4D classes are given in this paper, and an example is given for the 5D and 6D cases, respectively. If necessary, the method introduced and explained here can also be applied to cases with higher dimensions. The application examples demonstrate the same mathematical structure of some physically different problems.

In addition, this treatment can be applied to pulse sequences in a manner similar to the POF. In some cases, an algebraic language program may be helpful. Even numerical computations can use this framework by starting the numerical computation 430 on the basis of existing analytical relations.

## Appendix A: Norms of spin operators

As proven in the SI (section 1.3), the norm of a product of the Cartesian components of  $n$  spins  $1/2$  (one operator for each spin) amounts to  $2^{N/2-n}$ . Furthermore, for the sum of two orthogonal operators  $\hat{A}$  and  $\hat{B}$  holds  $\|\hat{A} + \hat{B}\| = \sqrt{\|\hat{A}\|^2 + \|\hat{B}\|^2}$ . From this, we can derive the following rules ( $\alpha, \beta, \gamma, \delta \in x, y, z$ ):

- 435
- For single spins  $I = \frac{1}{2}$ :  $\|\hat{I}_\alpha\| = \frac{1}{\sqrt{2}}$ ;
  - For spin pairs  $I = \frac{1}{2}, S = \frac{1}{2}$ :  $\|\hat{I}_\alpha\| = \|\hat{S}_\alpha\| = 1$ ;  $\|\hat{I}_\alpha \hat{S}_\beta\| = \frac{1}{2}$ ;  $\|\hat{I}_\alpha \hat{S}_\beta \pm \hat{I}_\gamma \hat{S}_\delta\| = \frac{1}{\sqrt{2}}$

– For spin triples  $I = \frac{1}{2}$ ,  $J = \frac{1}{2}$ ,  $S = \frac{1}{2}$ :

$$\|\hat{I}_\alpha\| = \|\hat{J}_\alpha\| = \|\hat{S}_\alpha\| = \sqrt{2}; \quad \|\hat{I}_\alpha\hat{S}_\beta\| = \frac{1}{\sqrt{2}}; \quad \|\hat{I}_\alpha\hat{S}_\beta \pm \hat{I}_\gamma\hat{S}_\delta\| = 1; \quad \|\hat{I}_\alpha\hat{J}_\beta\hat{S}_\gamma\| = \frac{1}{2\sqrt{2}}$$

Similarly, for a single spin  $I = 1$  can be obtained:

$$440 \quad \|\hat{I}_\alpha\| = \sqrt{2}; \quad \|\hat{I}_\alpha\hat{I}_\beta + \hat{I}_\beta\hat{I}_\alpha\| = \sqrt{2}$$

## Appendix B: Hamiltonians used in the main part and in the SI

– Interaction of the I and S spins with the rf field, strengths  $\omega_{1I}$  and  $\omega_{1S}$ , respectively, assumed to be constant and parallel to the x axis in the rotating frame:

$$\hat{H}_{Ix} = -\omega_{1I}\hat{I}_x; \quad \hat{H}_{Sx} = -\omega_{1S}\hat{S}_x \quad (B1)$$

445 Unless otherwise indicated, the irradiation occurs at the Larmor frequency of the respective spins. The rf phase is always such that  $\mathbf{B}_1$  is parallel to the x axis of the rotating frame, but the calculations can easily be modified to include other directions of the rf field.

– Homonuclear dipolar interaction between spin  $\mathbf{I}_1$  and spin  $\mathbf{I}_2$  (secular part):

$$\hat{H}_{II} = D_{II} (\hat{\mathbf{I}}_1\hat{\mathbf{I}}_2 - 3\hat{I}_{1z}\hat{I}_{2z}) \quad (B2)$$

450 where  $D_{II} = (\mu_0\gamma_I^2\hbar/(4\pi r_{II}^3)) (3\cos^2\theta_{II} - 1)$ ,  $r_{II}$  is the length of the vector connecting both spins and  $\theta_{II}$  is the angle of this vector with the external magnetic field,  $\gamma_I$  is the gyromagnetic ratio of the I spins and  $\mu_0$  is the permeability of the vacuum.

– Heteronuclear dipolar interaction between spin  $\mathbf{I}$  and spin  $\mathbf{S}$  (secular part):

$$\hat{H}_{IS} = -D_{IS} \cdot 2\hat{I}_z\hat{S}_z \quad (B3)$$

455 where  $D_{IS} = \frac{\mu_0}{4\pi} \frac{\hbar\gamma_I\gamma_S}{r_{IS}^3} (3\cos^2\theta_{IS} - 1)$ ,  $r_{IS}$  is the length of the vector connecting both spins and  $\theta_{IS}$  is the angle of this vector with the external magnetic field,  $\gamma_S$  is the gyromagnetic ratio of the S spins. The case of J coupling between unlike spins is mathematically equivalent to this; the corresponding formulae can be obtained by replacing  $D_{IS}$  by  $-\pi J$ .

– Matched Hartmann-Hahn cross polarization between spin I and spin S in the double-rotating frame (Hartmann and Hahn, 1962):

$$460 \quad \hat{H}_{HH} = -D_{IS} \cdot (\hat{I}_x\hat{S}_x + \hat{I}_y\hat{S}_y) \quad (B4)$$

assuming  $D_{IS} \ll \omega_{1I,S}$  so that rapidly oscillating terms can be neglected.

- Interaction of first order of the nuclear quadrupole moment with the electric field gradient (secular part):

$$\hat{H}_Q = \omega_Q \cdot \left( \hat{I}_z^2 - \frac{I(I+1)}{3} \right) \quad (\text{B5})$$

where  $\omega_Q$  is the quadrupolar frequency.

- 465 – Resonance offset  $\Delta\omega$  in the rotating frame:

$$\hat{H}_\Delta = -\Delta\omega \hat{I}_z \quad (\text{B6})$$

The coupling frequencies are assumed to be unique, i.e. no powder averaging unless otherwise stated. It is also assumed that the coupling frequencies are constant in time, i.e. thermal motion or sample rotation is not considered.

470 *Author contributions.* The author G.H. developed the method, derived by that the examples given here and compared them with known equations, if any.
