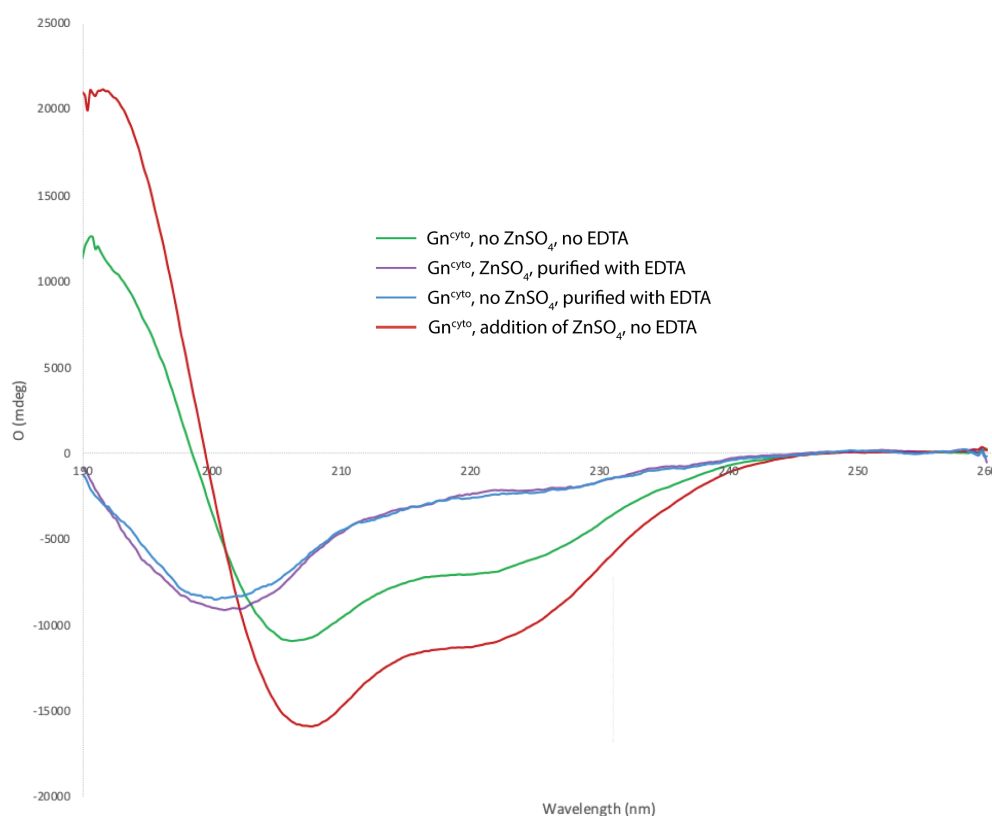

Figure S1: Circular dichroism spectra of Gn^{cyto} showing that addition of EDTA causes loss of secondary structure content due to Zn²⁺ depletion, both when synthesized in the presence (purple line) or in the absence (blue line) of ZnSO₄. When the protein is synthesized without addition of ZnSO₄, secondary structure is observed (green curve), likely by use of ions present in the extract, but the features are less pronounced than when ZnSO₄ is added to the cell-free reaction (red curve).

Figure S2: Comparison between the ^{15}N HSQC spectrum recorded on the CFPS Gn^{cyto} sample in red, compared to a simulation using the chemical shifts deposited in the BMRB 17383 (Estrada and De Guzman, 2011). The sequences of the analyzed proteins are shown in Figure S3.

Figure S3: CSPs, calculated according to $CSP =$

$$\sqrt{(\partial^1 H_1 - \partial^1 H_2)^2 + \left(\frac{\gamma^{15N}}{\gamma^1 H} (\partial^{15} N_1 - \partial^{15} N_2) \right)^2},$$

where $\partial^1 H$ stands for the amide proton chemical shift, $\partial^{15} N$ is the amide nitrogen chemical shift, γ^{15N} is the gyromagnetic ratio of nitrogen and $\gamma^1 H$ the proton gyromagnetic ratio. Differences in the amino-acid sequence are highlighted.
